Determination of QGP Parameters from a Global Bayesian Analysis

Steffen A. Bass

http://www.facebook.com/DukeQCD

@Steffen_Bass

Properties of QCD: Transport Coefficients

shear and bulk viscosity are defined as the coefficients in the expansion of the stress tensor in terms of the velocity fields:

$$T_{ik} = \varepsilon u_i u_k + P\left(\delta_{ik} + u_i u_k\right) - \eta \left(\nabla_i u_k + \nabla_k u_i - \frac{2}{3}\delta_{ik} \nabla \cdot u \right) + \varsigma\, \delta_{ik} \nabla \cdot u$$

η/s from Lattice QCD:

The confines of the Euklidian Formulation:

- extracting η/s formally requires taking the zero momentum limit in an infinite spatial volume, which is numerically not possible…

•preliminary estimates:

T	1.58 T_C	2.32 T_C
η/s	0.2-0.25	0.25-0.5

A. Nakamura & S. Sakai: Phys. Rev. Lett. **94** (2005) 072305

The determination of the QCD transport coefficients is one of the key goals of the global relativistic heavy-ion effort!

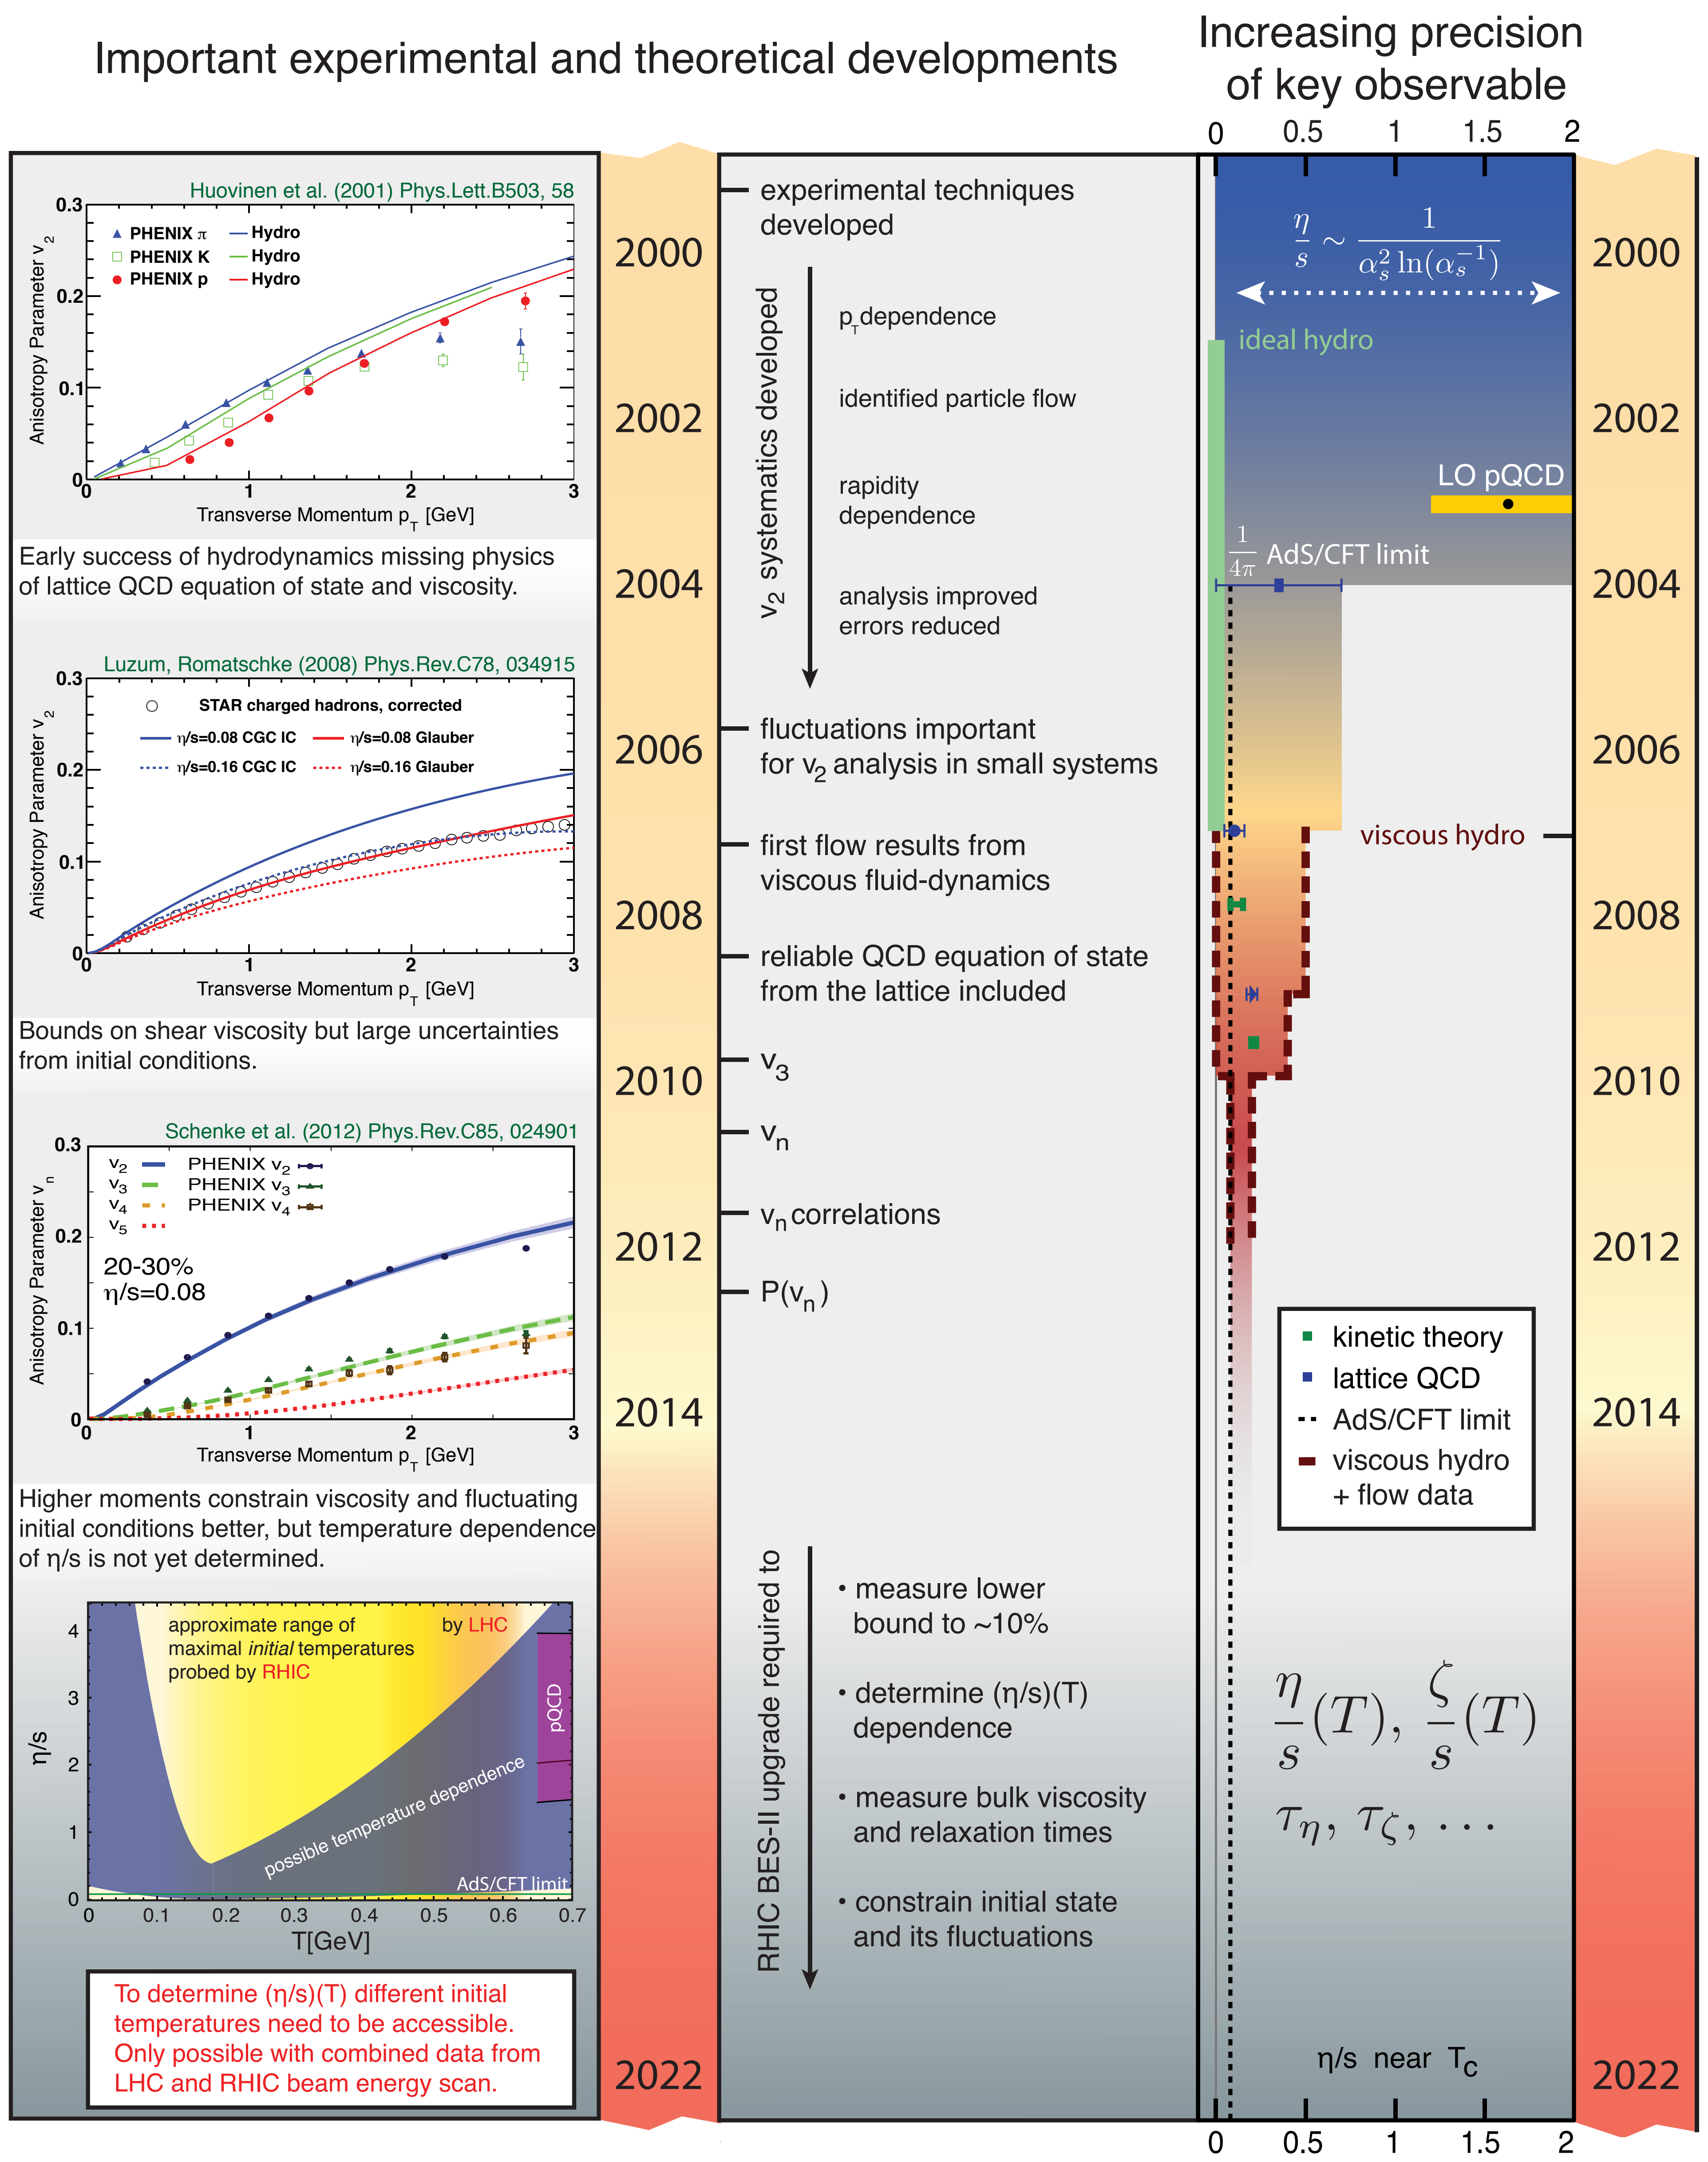
An Effort by the Heavy-Ion Community

2012 response of the US relativistic heavy-ion community to the request for comments by the NSAC subcommittee, that was tasked to recommend *optimizations* to the US Nuclear Science Program over the following five years.

2012 RHIC community White Paper identified key developments and laid out milestones for the determination of QGP properties:

Goal: by 2022 determine the temperature dependence of η/s and ζ/s as well as relaxation times and other QGP transport coefficients of interest (e.g. q-hat and e-hat)

We are well on our way deliver on these goals!



Standing on the Shoulders of Giants

PRL **97,** 152303 (2006) PHYSICAL REVIEW LETTERS week ending 13 OCTOBER 2006

Strongly Interacting Low-Viscosity Matter Created in Relativistic Nuclear Collisions

(Received 12 April 2006; published 12 October 2006)

Substantial collective flow is observed in collisions between large nuclei at BNL RHIC (Relativistic Heavy Ion Collider) as evidenced by single-particle transverse momentum distributions and by azimuthal correlations among the produced particles. The data are well reproduced by perfect fluid dynamics. A calculation of the dimensionless ratio of shear viscosity η to entropy density s by Kovtun, Son, and Starinets within anti-de Sitter space/conformal field theory yields $\eta/s = \hbar/4\pi k_B$, which has been conjectured to be a lower bound for any physical system. Motivated by these results, we show that the transition from hadrons to quarks and gluons has behavior similar to helium, nitrogen, and water at and near their phase transitions in the ratio η/s. We suggest that experimental measurements can pinpoint the location of this transition or rapid crossover in QCD.

ALICE

Transport Theory:
Connecting Data to Knowledge

Transport Theory

microscopic transport models based on the **Boltzmann Equation**:

- transport of a system of microscopic particles
- all interactions are based on binary scattering

$$\left[\frac{\partial}{\partial t} + \frac{\vec{p}}{E} \times \frac{\partial}{\partial \vec{r}}\right] f_1(\vec{p},\vec{r},t) = \sum_{processes} C(\vec{p},\vec{r},t)$$

diffusive transport models based on the **Langevin Equation**:

- transport of a system of microscopic particles in a thermal medium
- interactions contain a drag term related to the properties of the medium and a noise term representing random collisions

$$\vec{p}(t+\Delta t) = \vec{p}(t) - \frac{\kappa}{2T}\vec{v}\cdot\Delta t + \vec{\xi}(t)\Delta t$$

(viscous) relativistic fluid dynamics:

- transport of macroscopic degrees of freedom
- based on conservation laws:

$$\partial_\mu T^{\mu\nu} = 0$$

$$\begin{aligned} T_{ik} &= \varepsilon u_i u_k + P\,(\delta_{ik} + u_i u_k) \\ &- \eta\left(\nabla_i u_k + \nabla_k u_i - \frac{2}{3}\delta_{ik}\nabla\cdot u\right) \\ &+ \varsigma\,\delta_{ik}\nabla\cdot u \end{aligned}$$

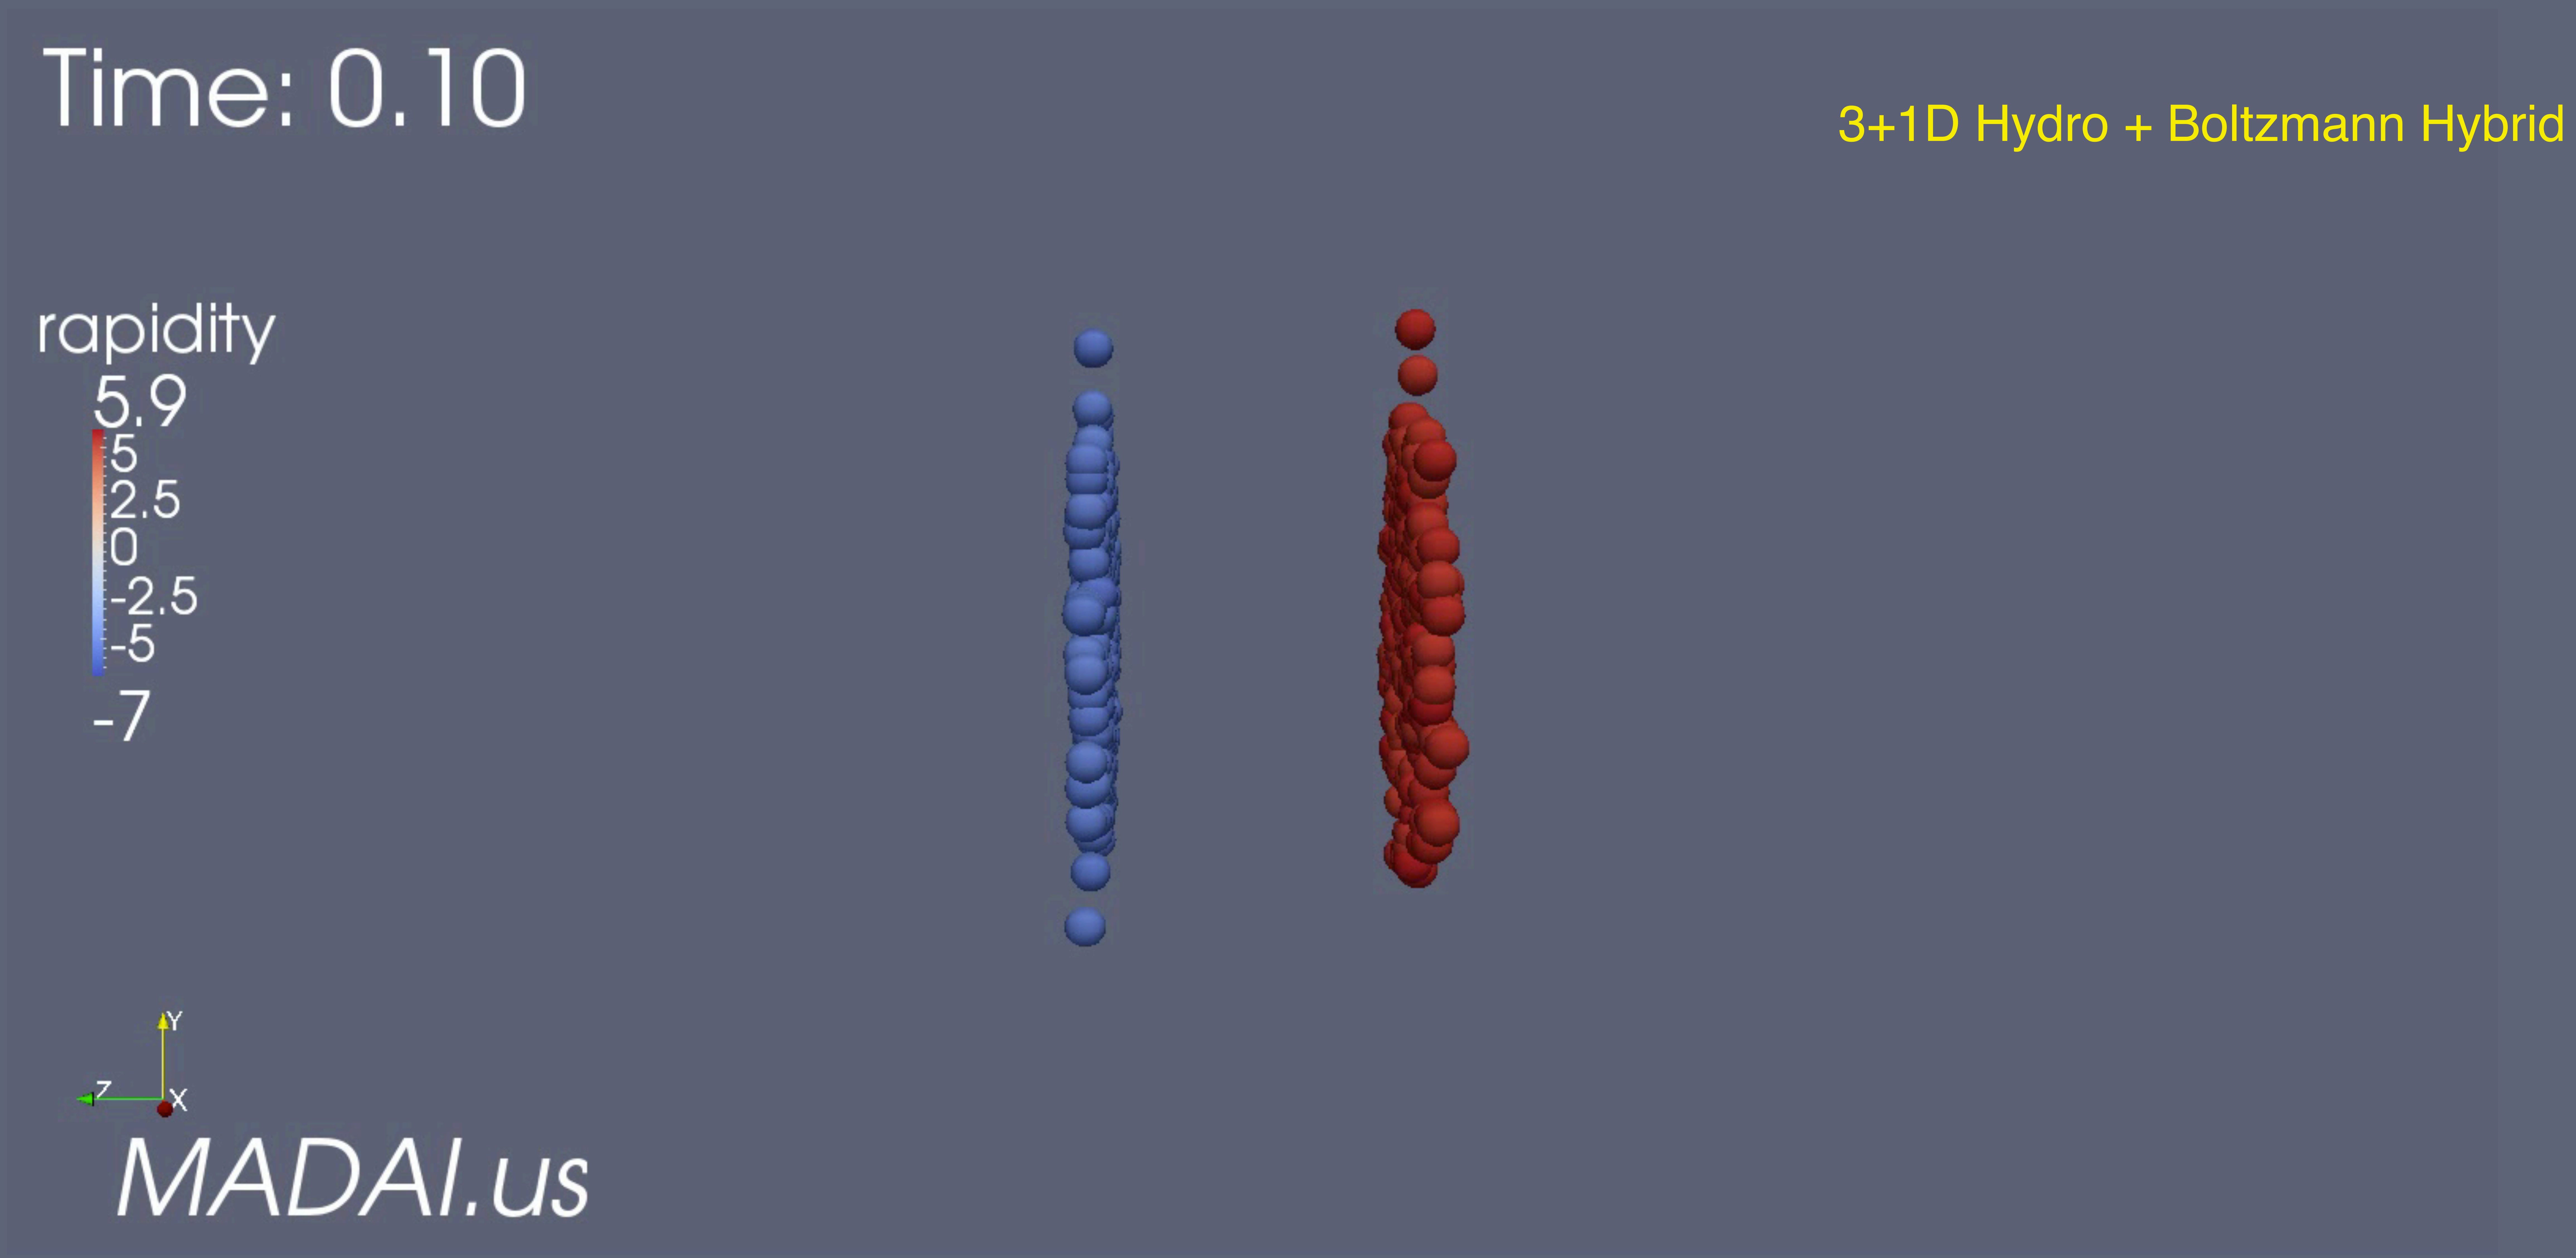
(plus an additional 9 eqns. for dissipative flows)

hybrid transport models:

- combine microscopic & macroscopic degrees of freedom
- current state of the art for RHIC modeling

Each transport model relies on roughly a dozen physics parameters to describe the time-evolution of the collision and its final state. These physics parameters act as a representation of the information we wish to extract from RHIC & LHC.

Computational Modeling



Probing the QGP in Relativistic Heavy-Ion Collisions

nuclei at 99.99% speed of light

Quark-Gluon-Plasma

hadronic final state interactions

measurable (stable) particles in detector

1x 10^{-23} s

10 x 10^{-23} s

30 x 10^{-23} s

non-equilibrium early time dynamics → viscous fluid dynamics → hadronic transport

Principal Challenges of Probing the QGP with Heavy-Ion Collisions:

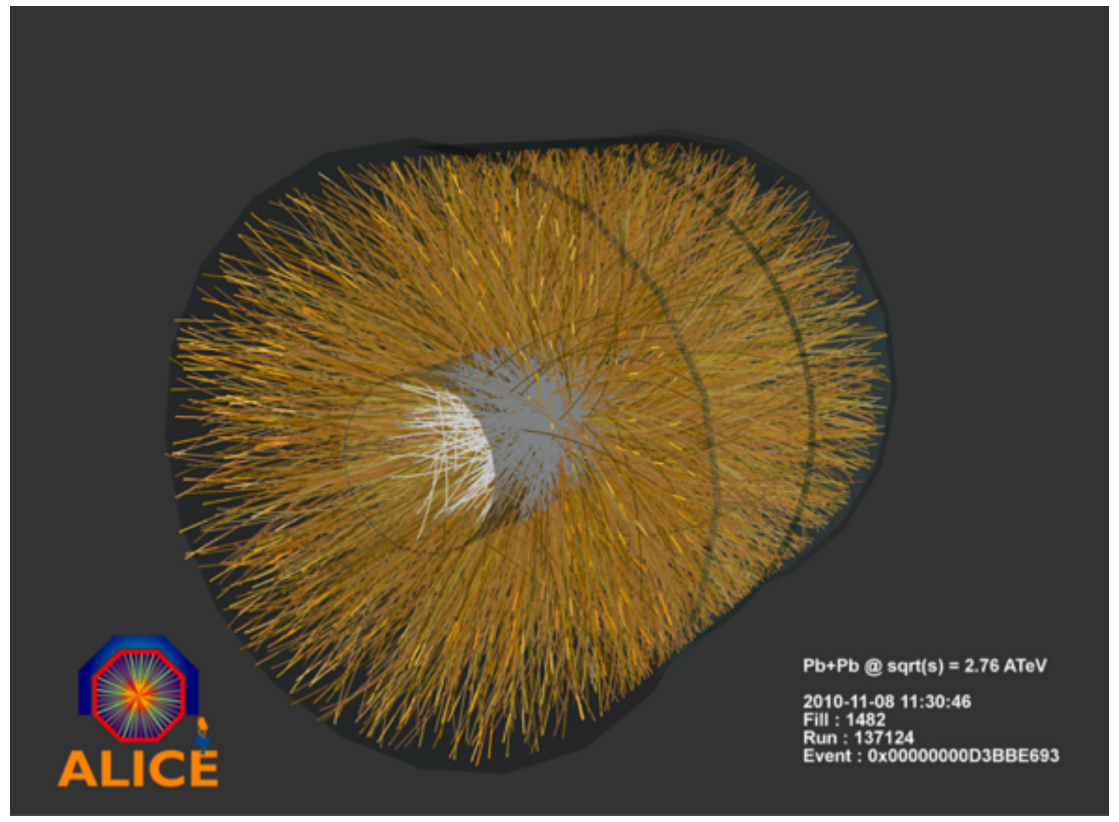
- time-scale of the collision process: 10^{-24} seconds! [too short to resolve]
- characteristic length scale: 10^{-15} meters! [too small to resolve]
- confinement: quarks & gluons form bound states, experiments don't observe them directly

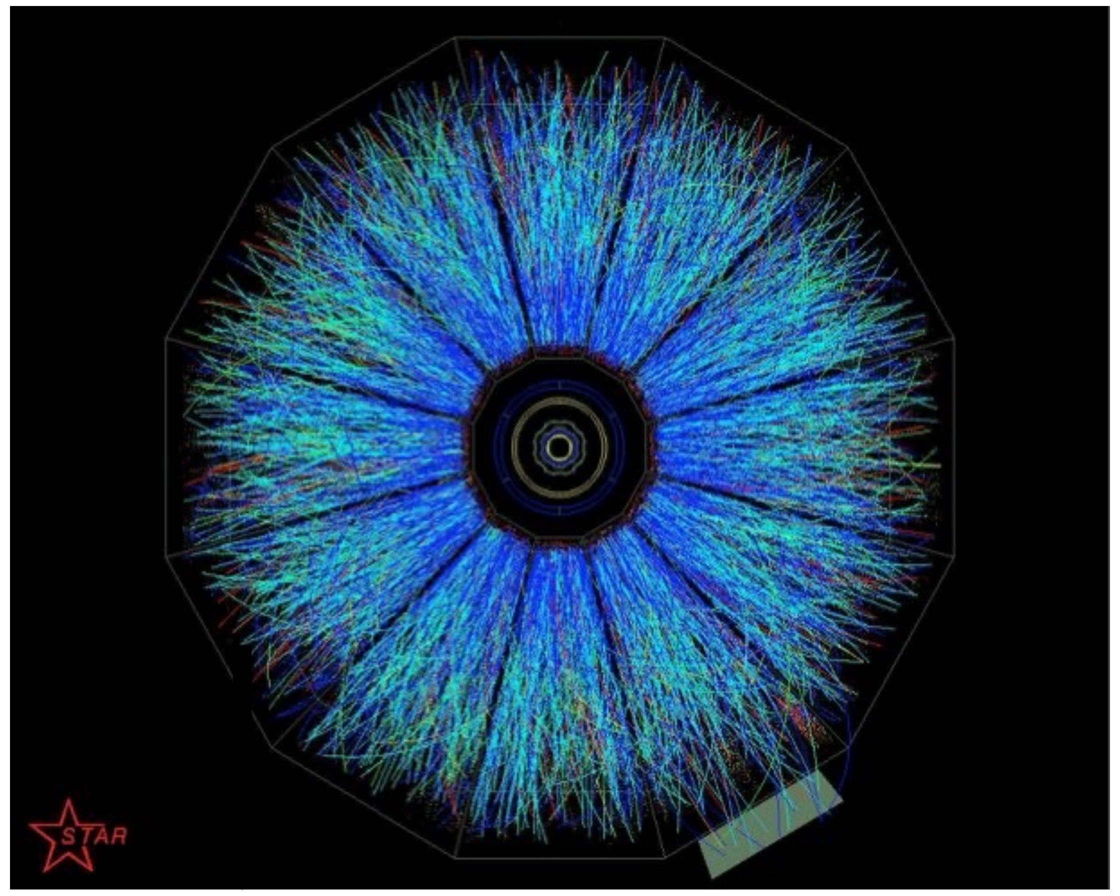
▸ **computational models are need to connect the experiments to QGP properties!**

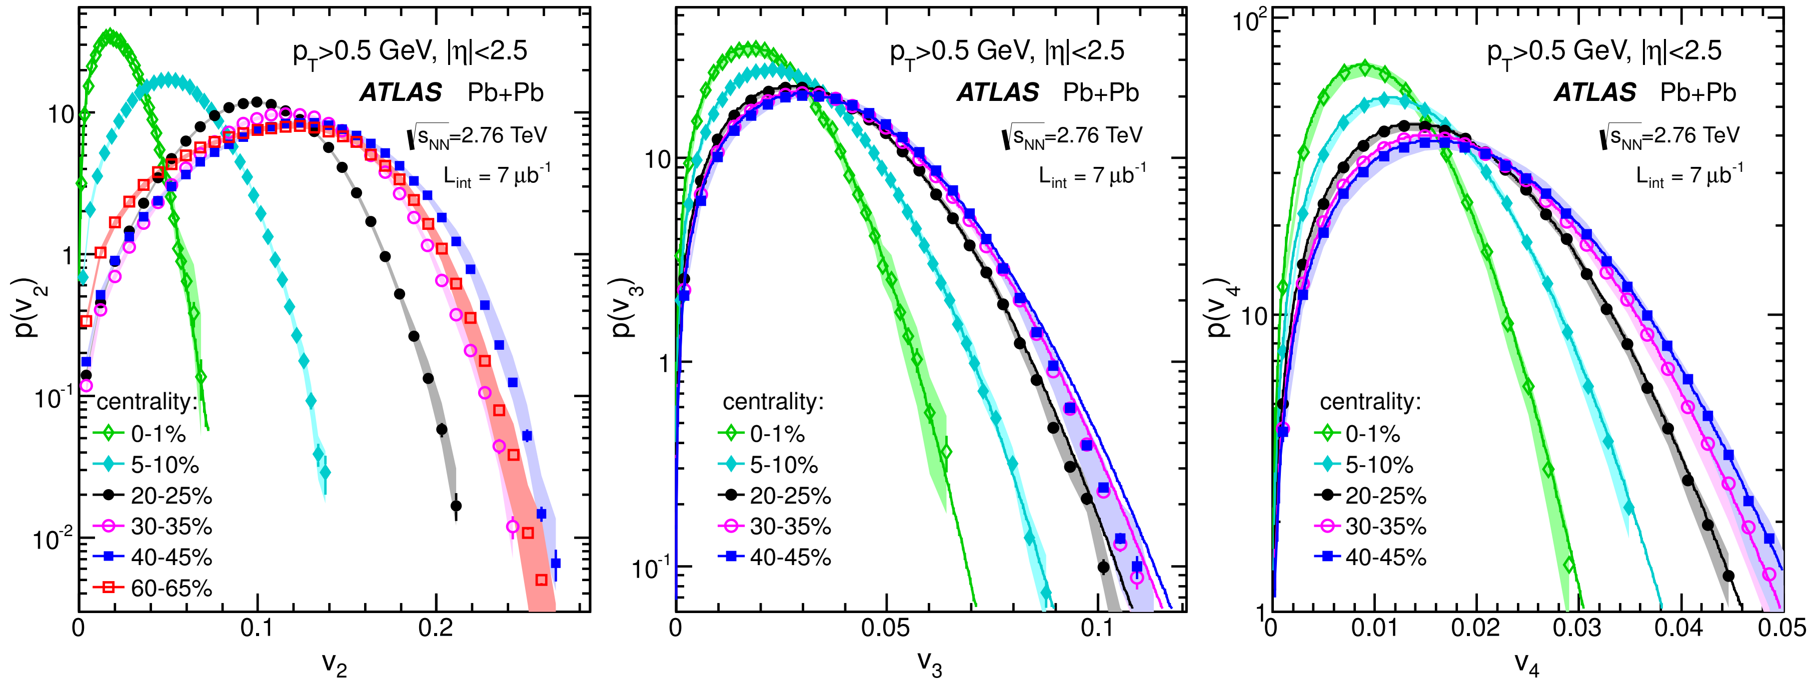
Knowledge Extraction from Relativistic Heavy-Ion Collisions

Probing QCD in Heavy-Ion Collisions

Data:

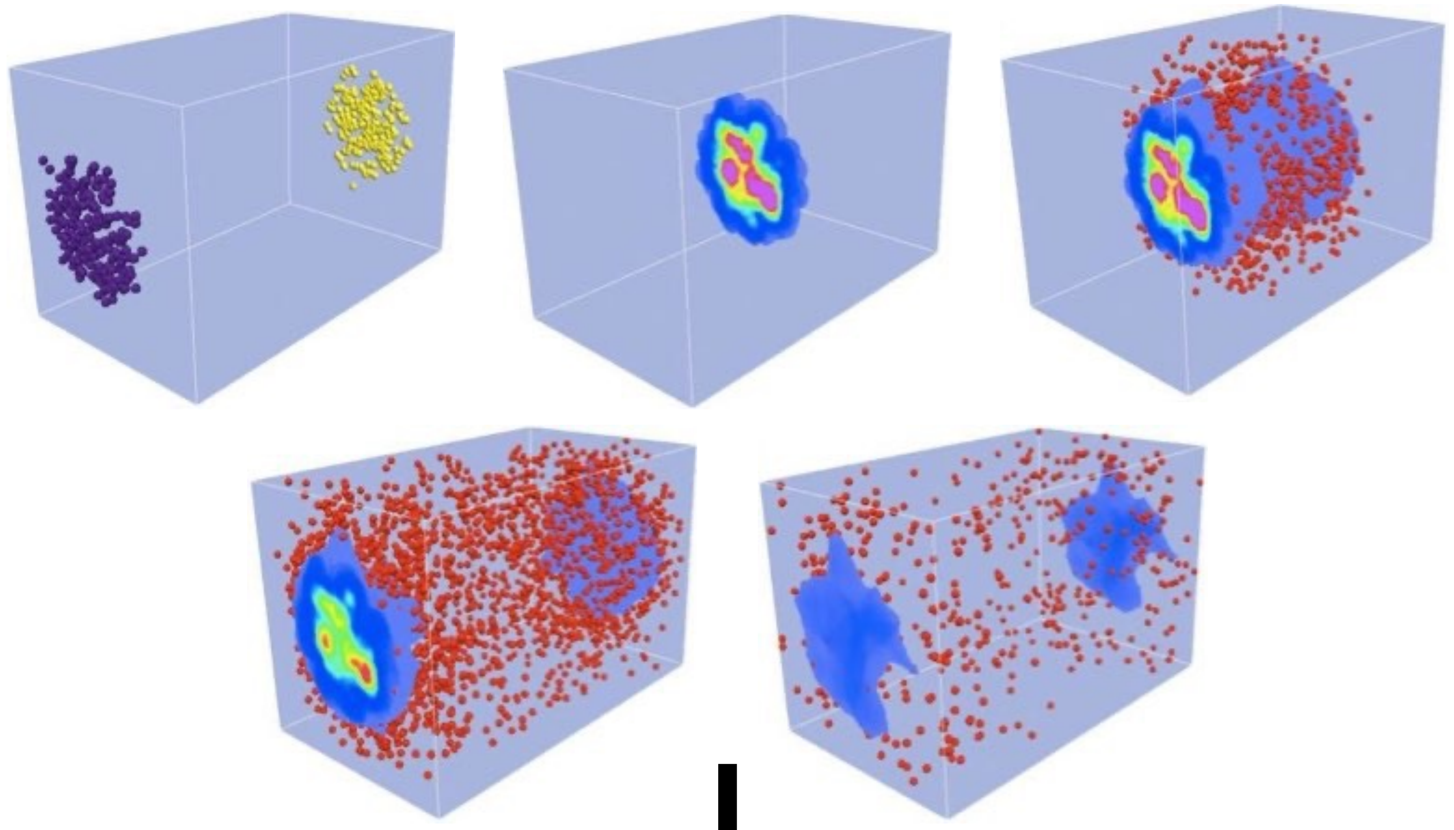


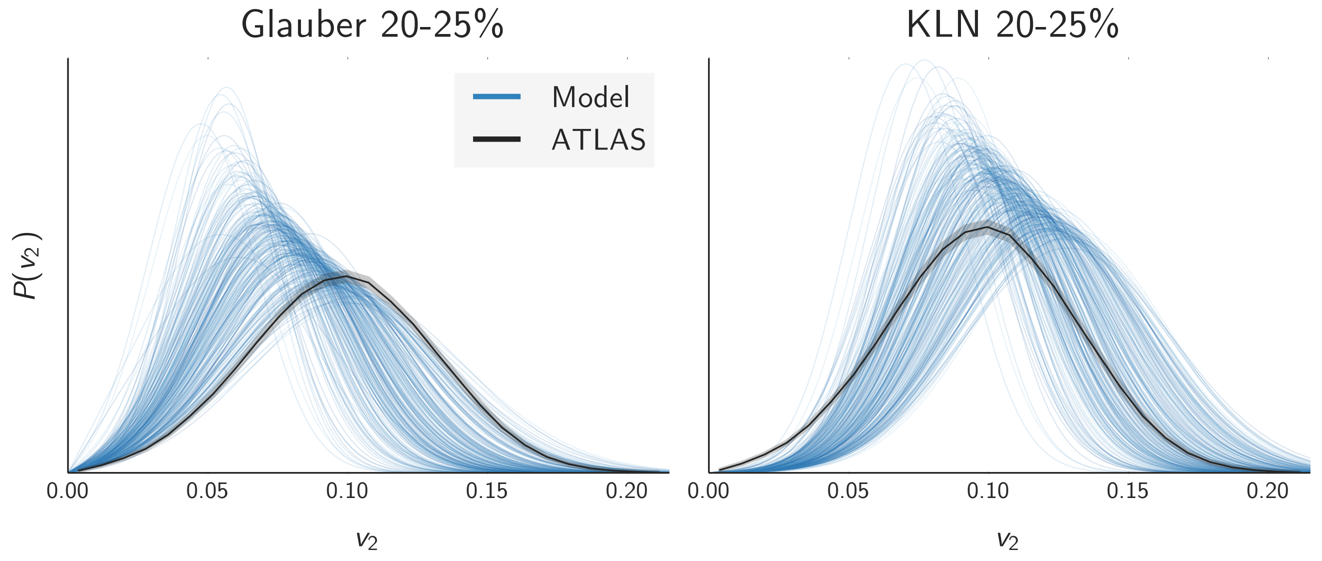




Model:

initial conditions, τ_0, η/s, ζ/s, ….



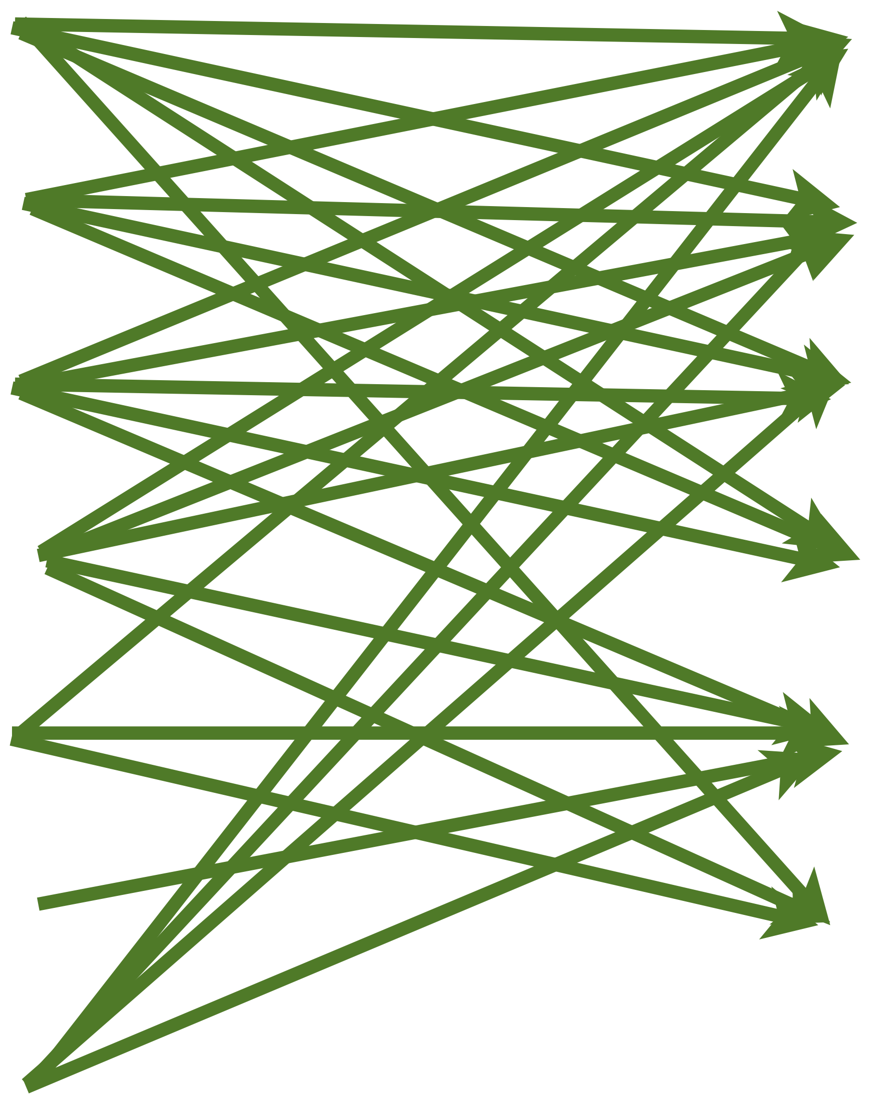


extracted QGP properties: η/s, …

Determining the QGP Properties via a Model to Data Comparison

Model Parameter:

- eqn. of state
- shear viscosity
- initial state
- pre-equilibrium dynamics
- thermalization time
- quark/hadron chemistry
- particlization/freeze-out



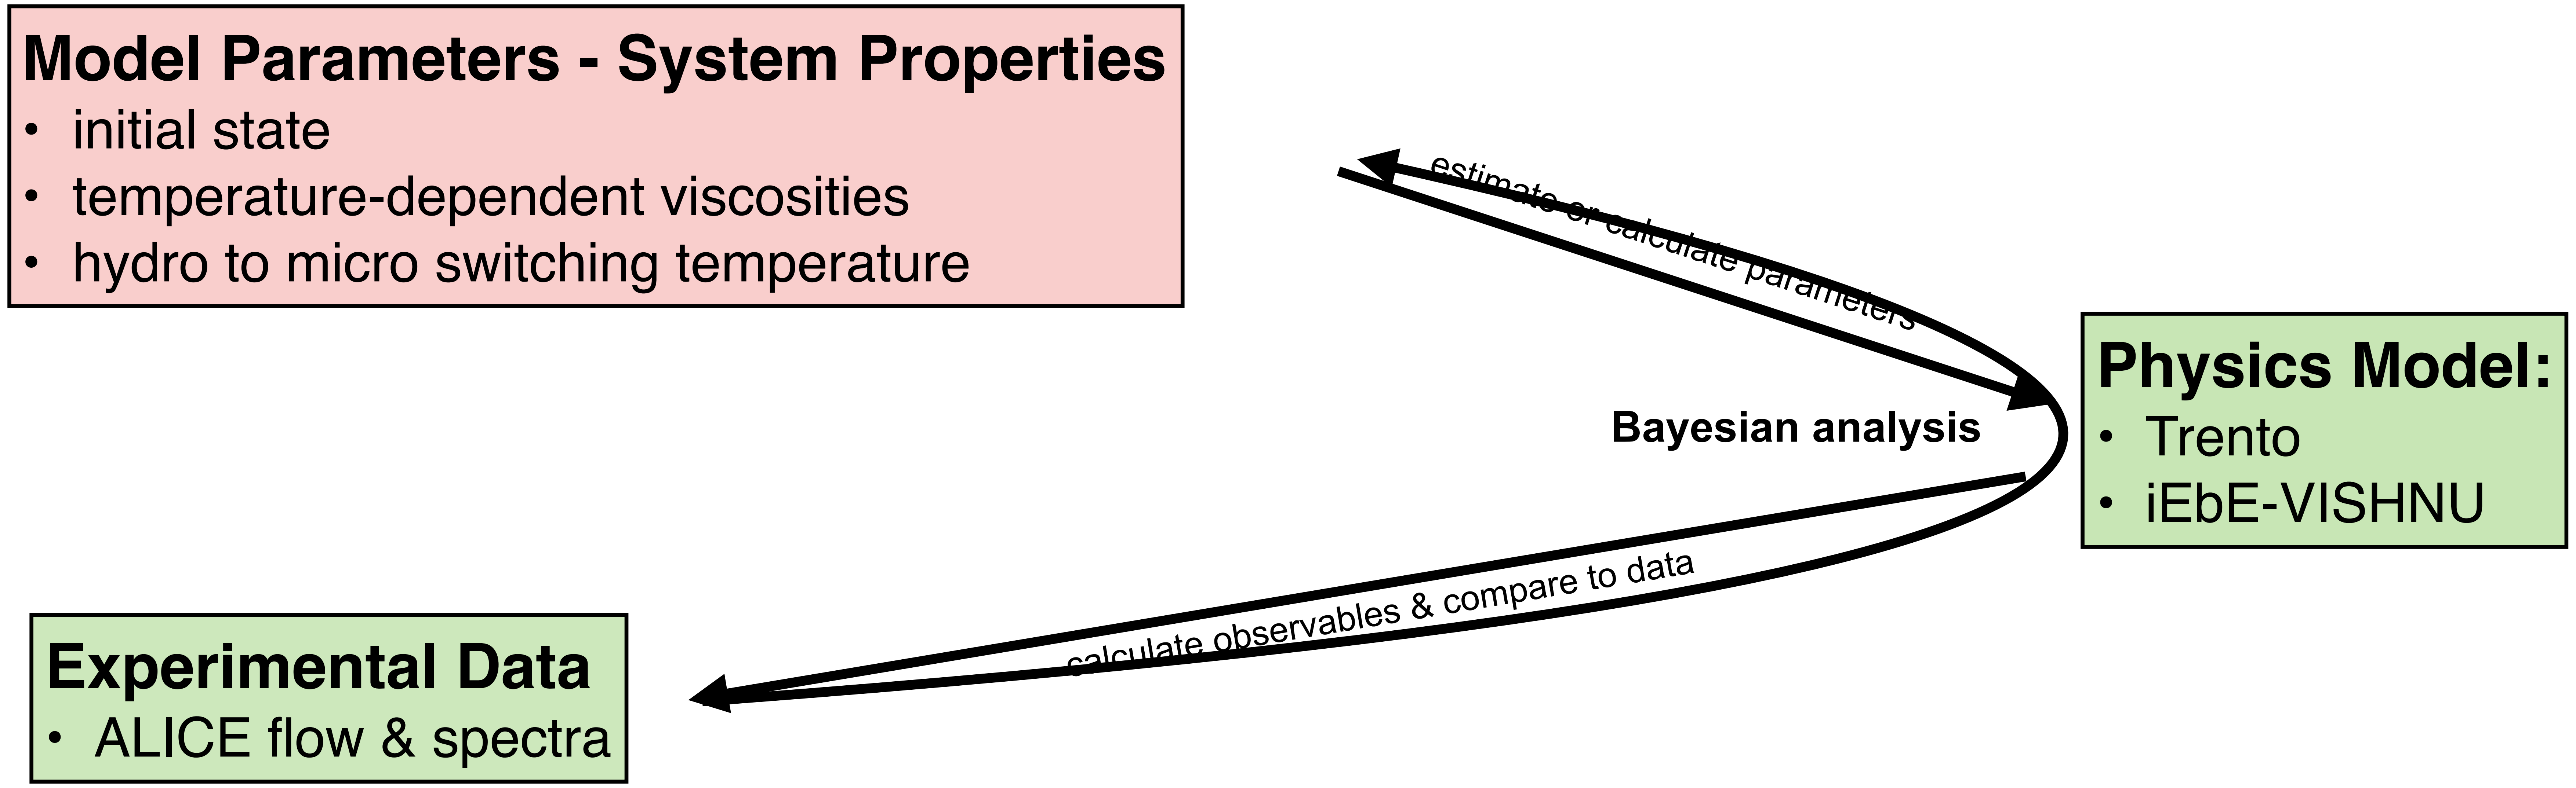
experimental data:

- π/K/P spectra
- yields vs. centrality & beam
- elliptic flow
- HBT
- charge correlations & BFs
- density correlations

- large number of interconnected parameters w/ non-factorizable data dependencies
- data have correlated uncertainties
- develop novel optimization techniques: Bayesian Statistics and MCMC methods
- transport models require too much CPU: need new techniques based on emulators
- general problem, not restricted to RHIC Physics →**collaboration with Statistical Sciences**

Bayesian Analysis

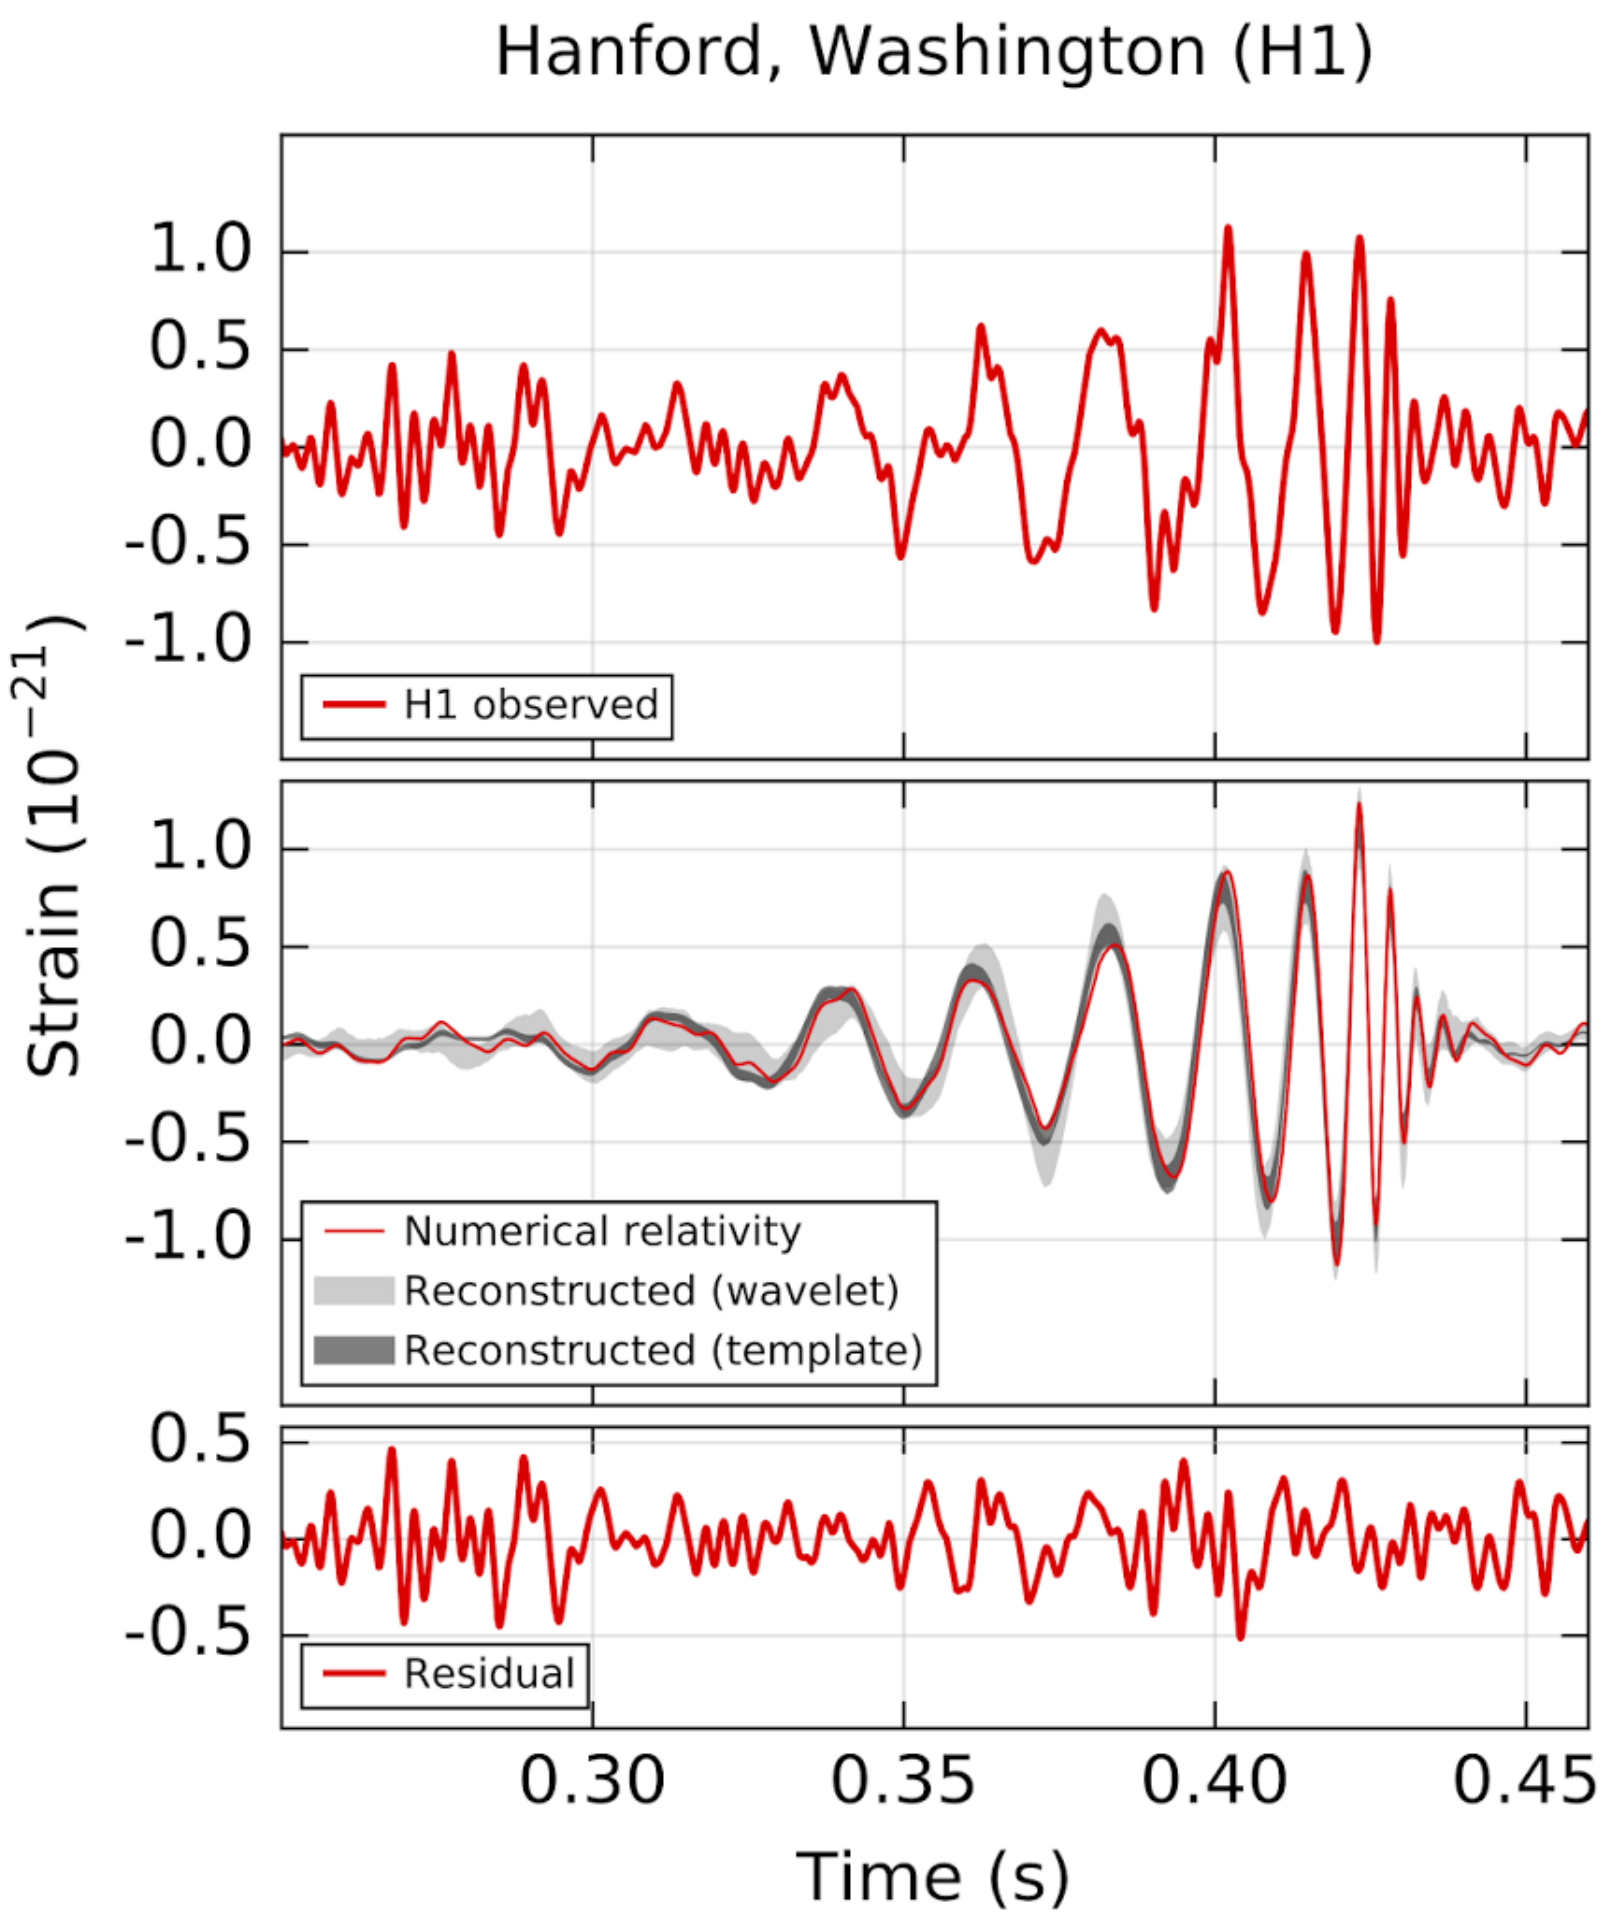
Each computational model relies on a set of physics parameters to describe the dynamics and properties of the system. These physics parameters act as a representation of the information we wish to extract from RHIC & LHC.



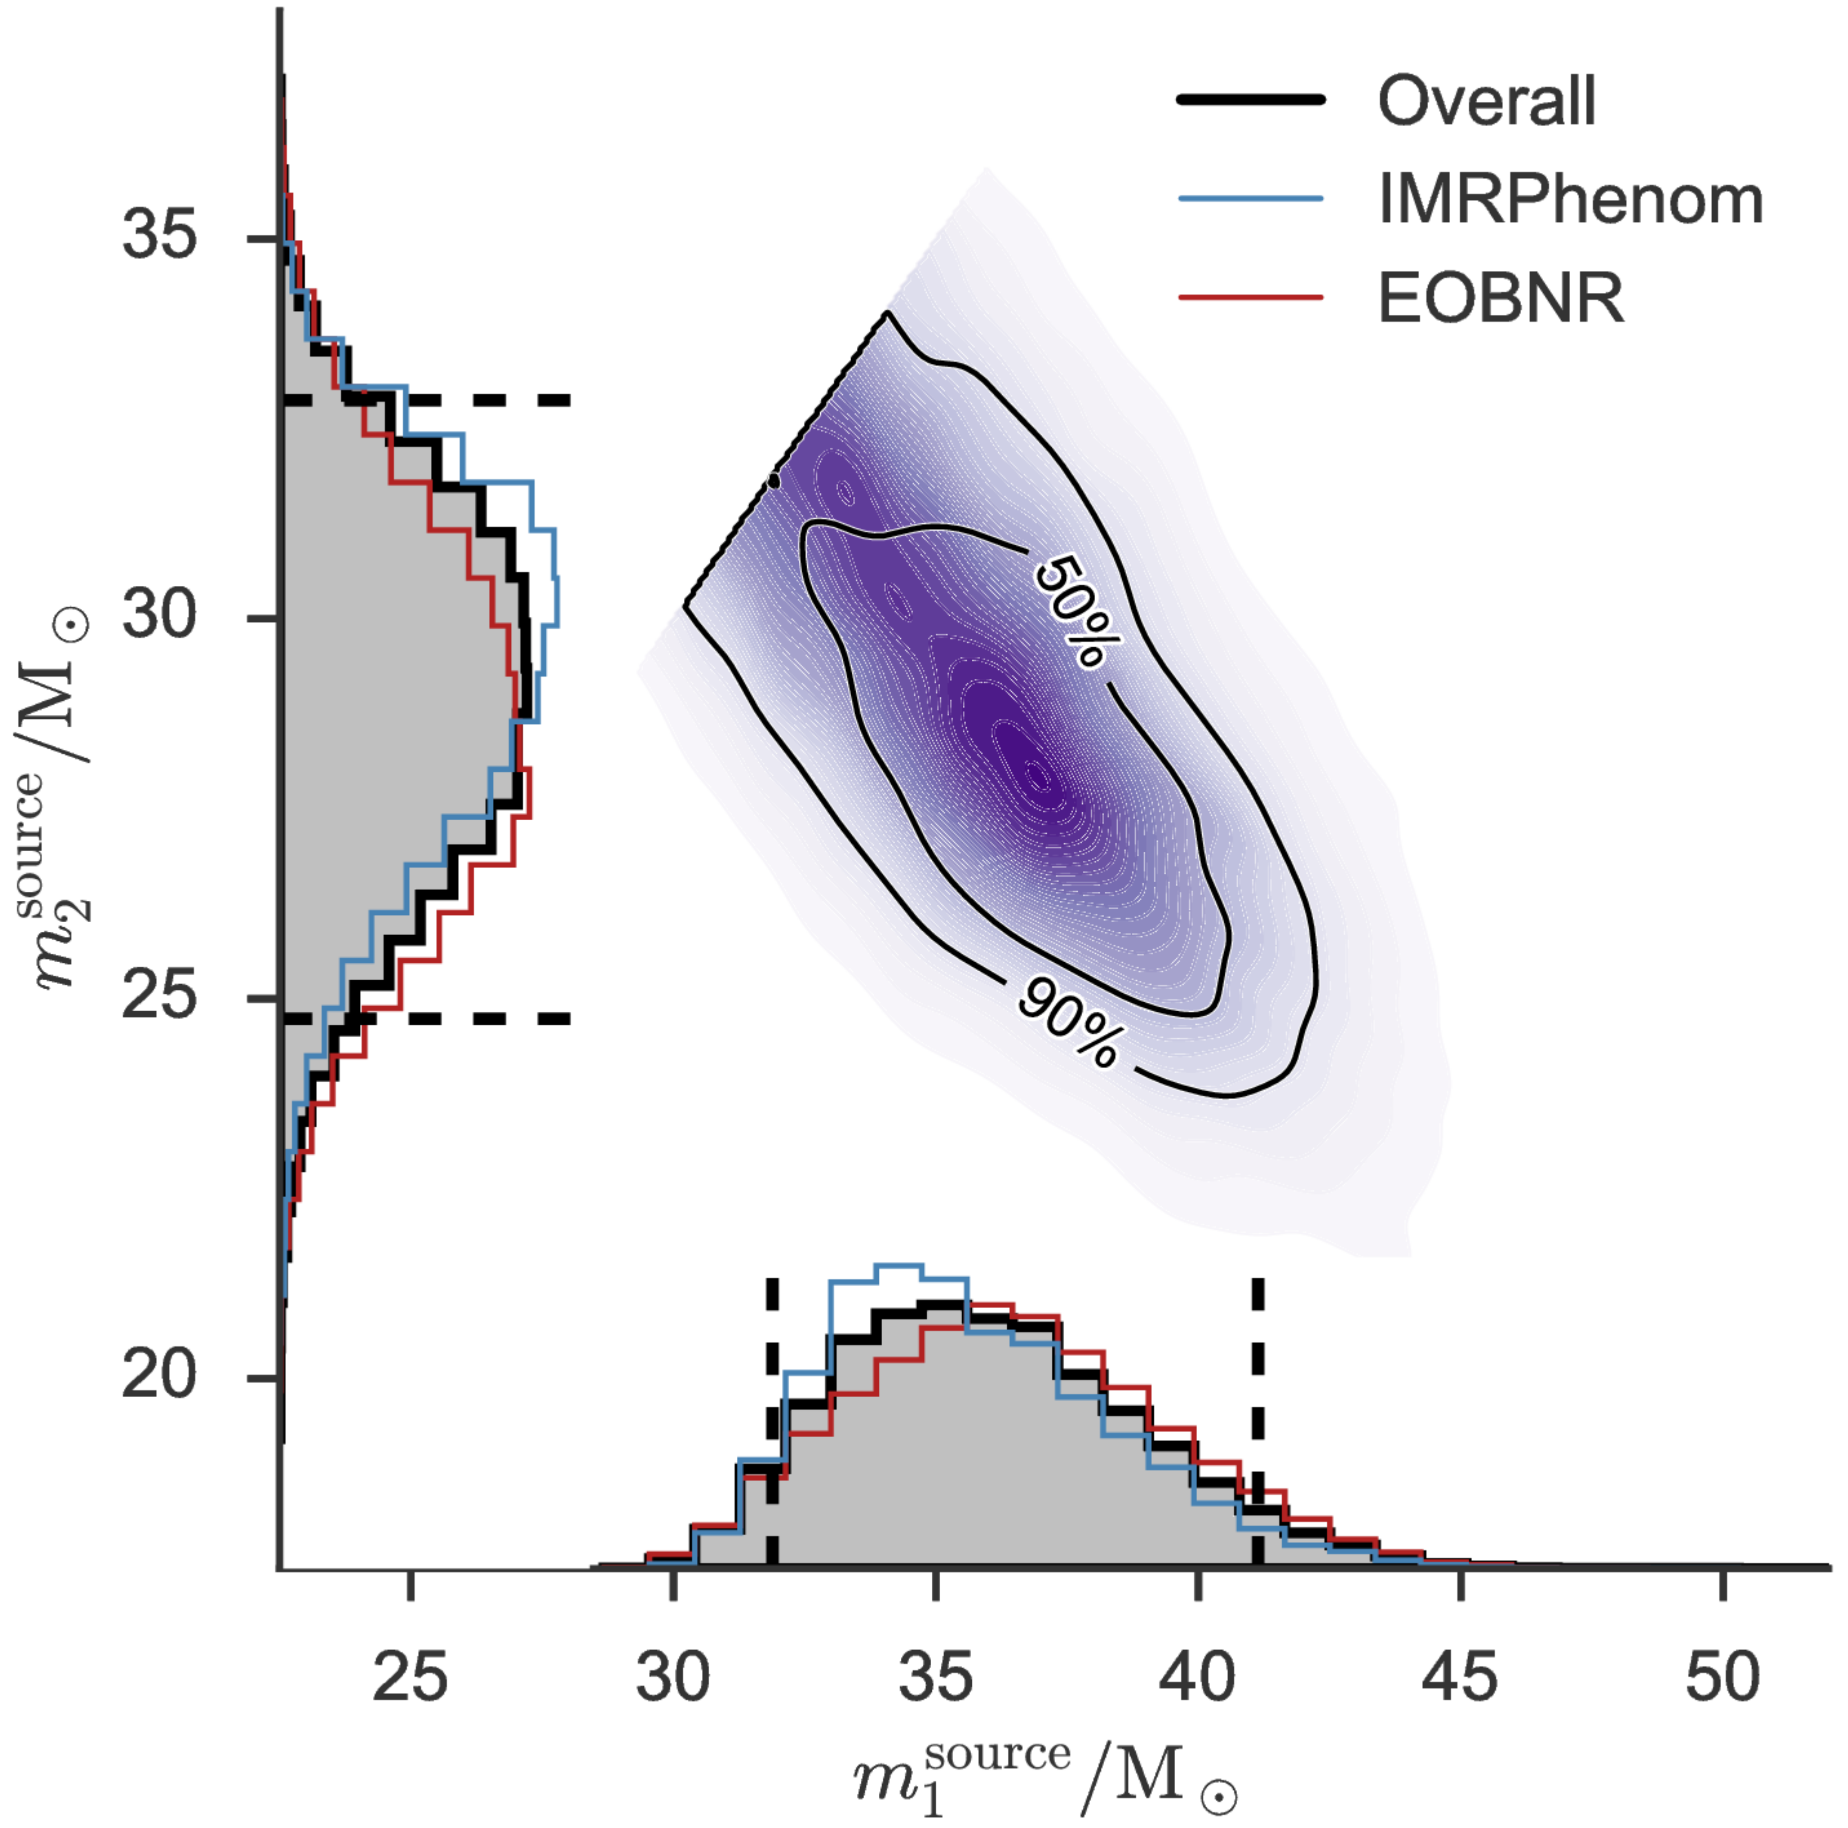
- Bayesian analysis allows us to simultaneously calibrate all model parameters via a model-to-data comparison
- determine parameter values such that the model best describes experimental observables
- extract the probability distributions of all parameters

Example: Gravitational Waves

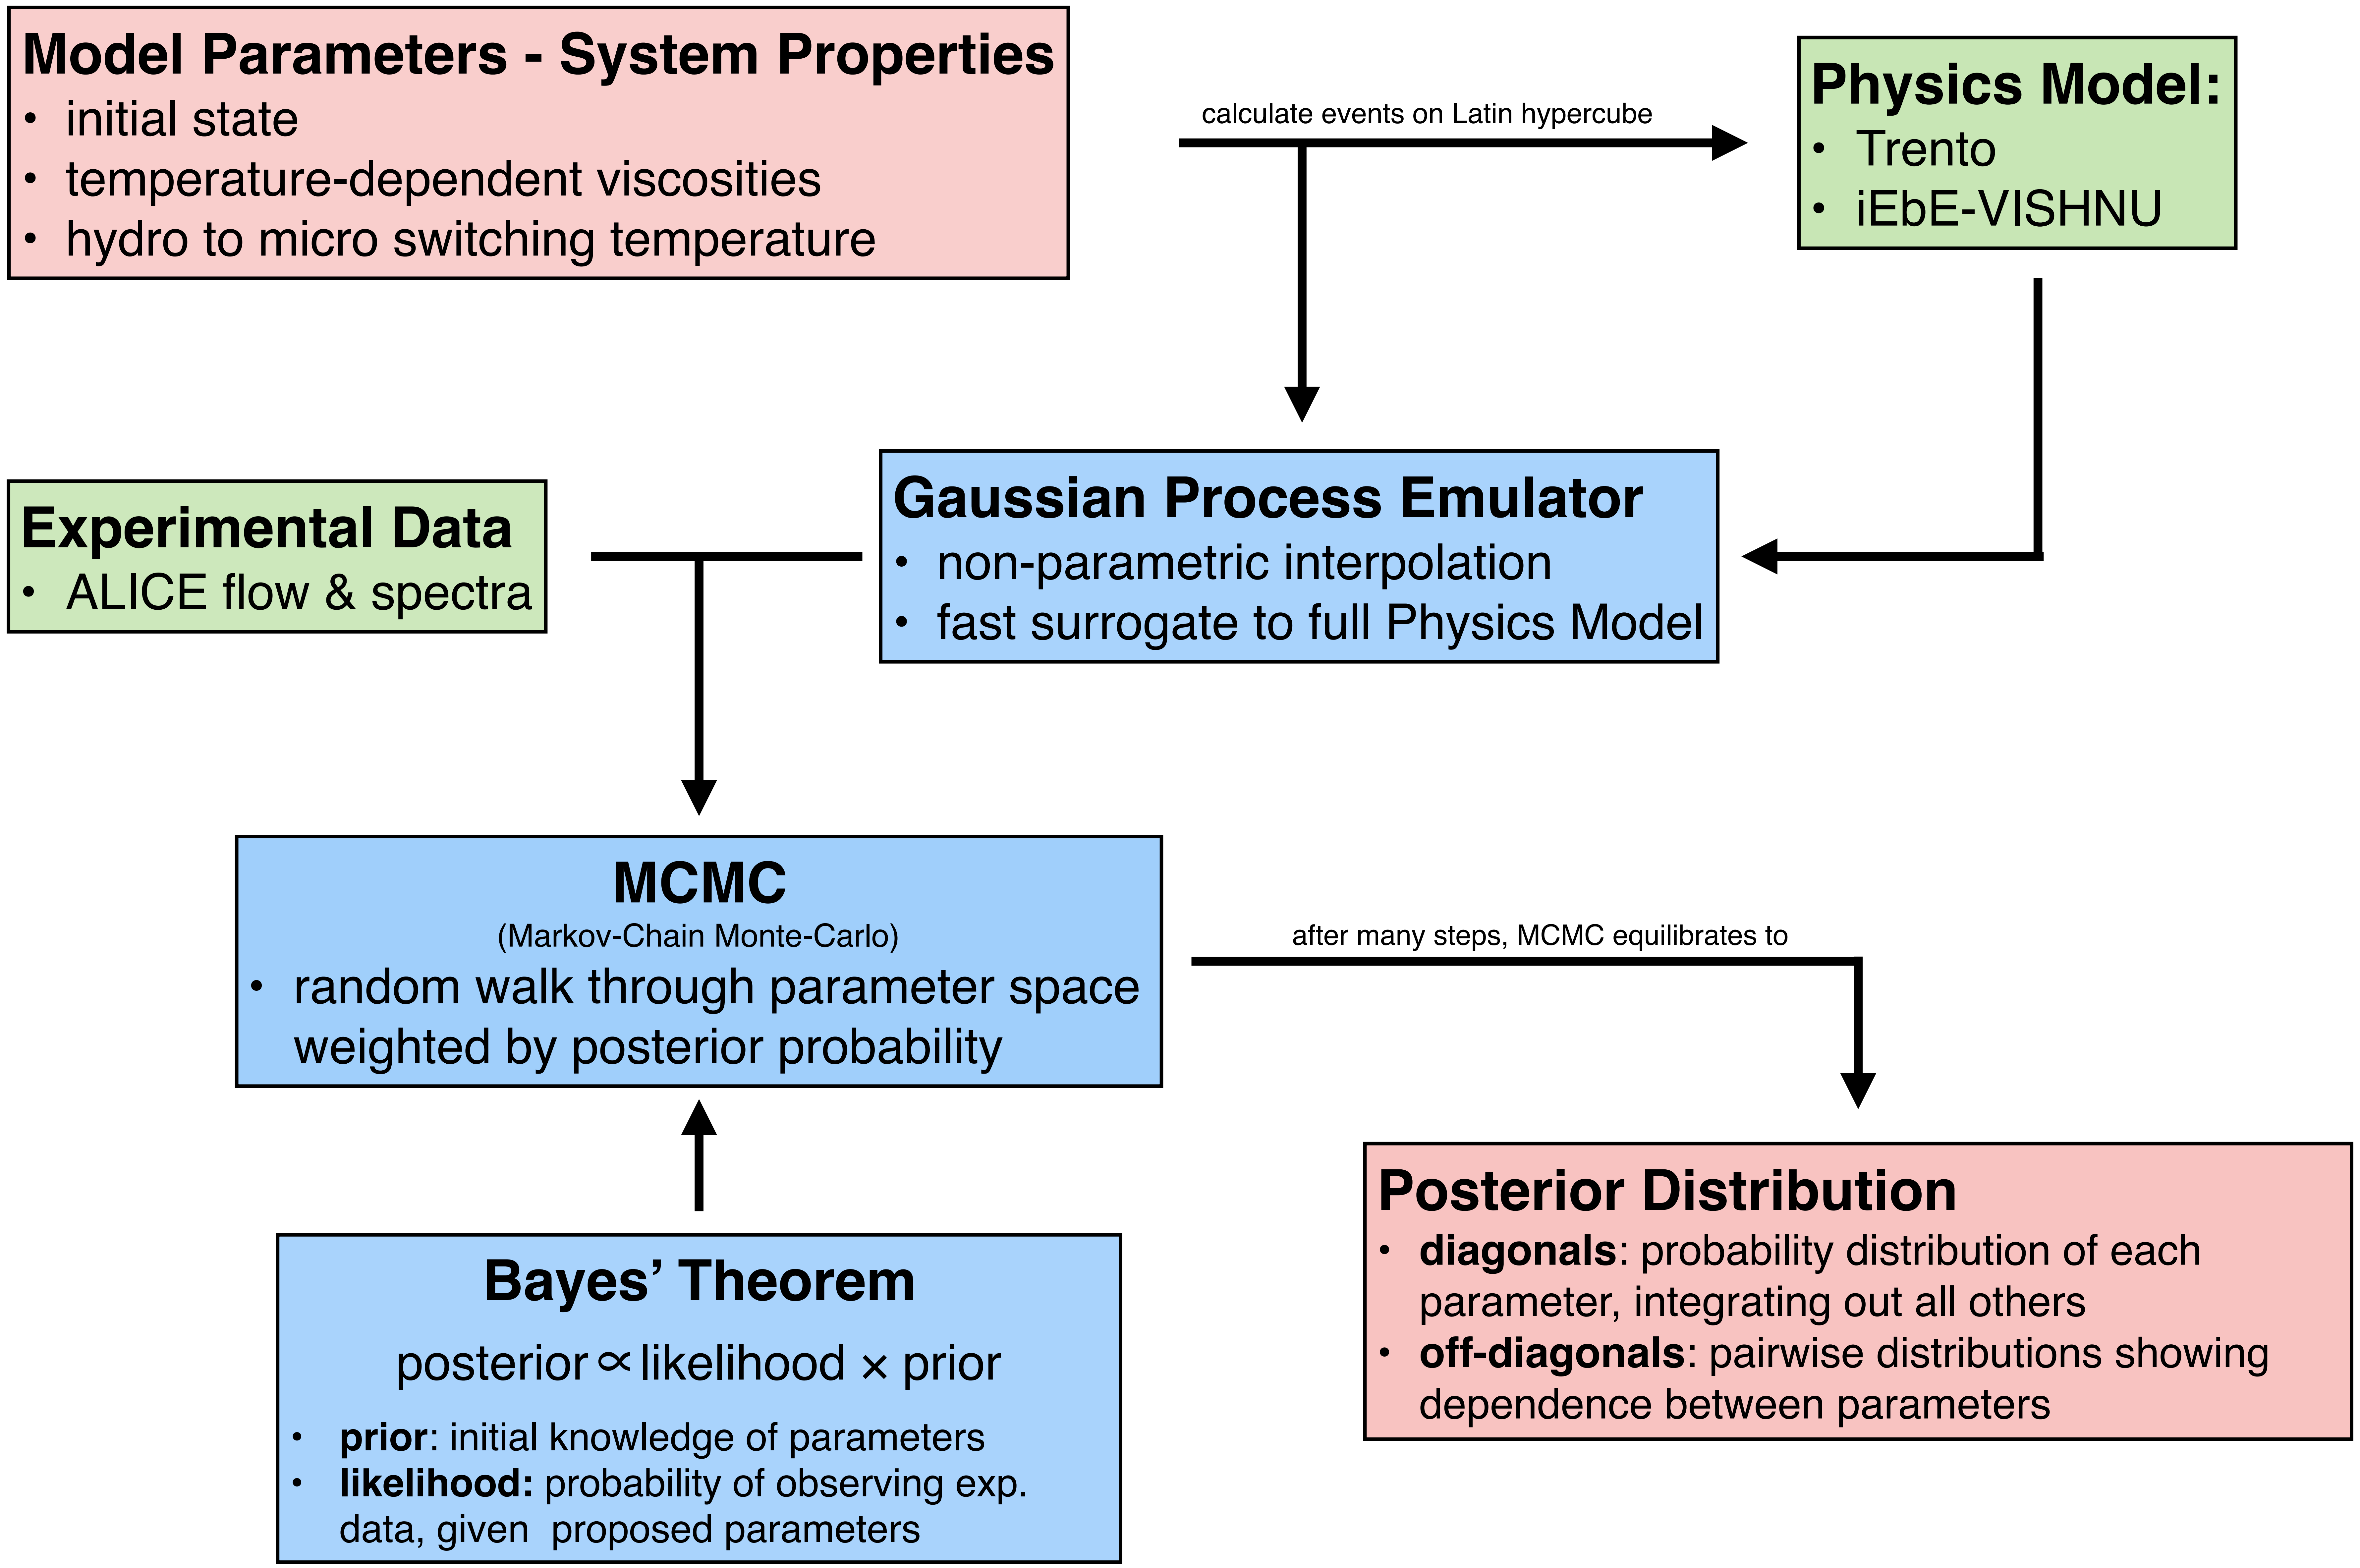
LIGO gravitational wave signal:



Bayesian analysis of GR model of merging black holes of masses m_1 and m_2 that is capable of reproducing LIGO data:

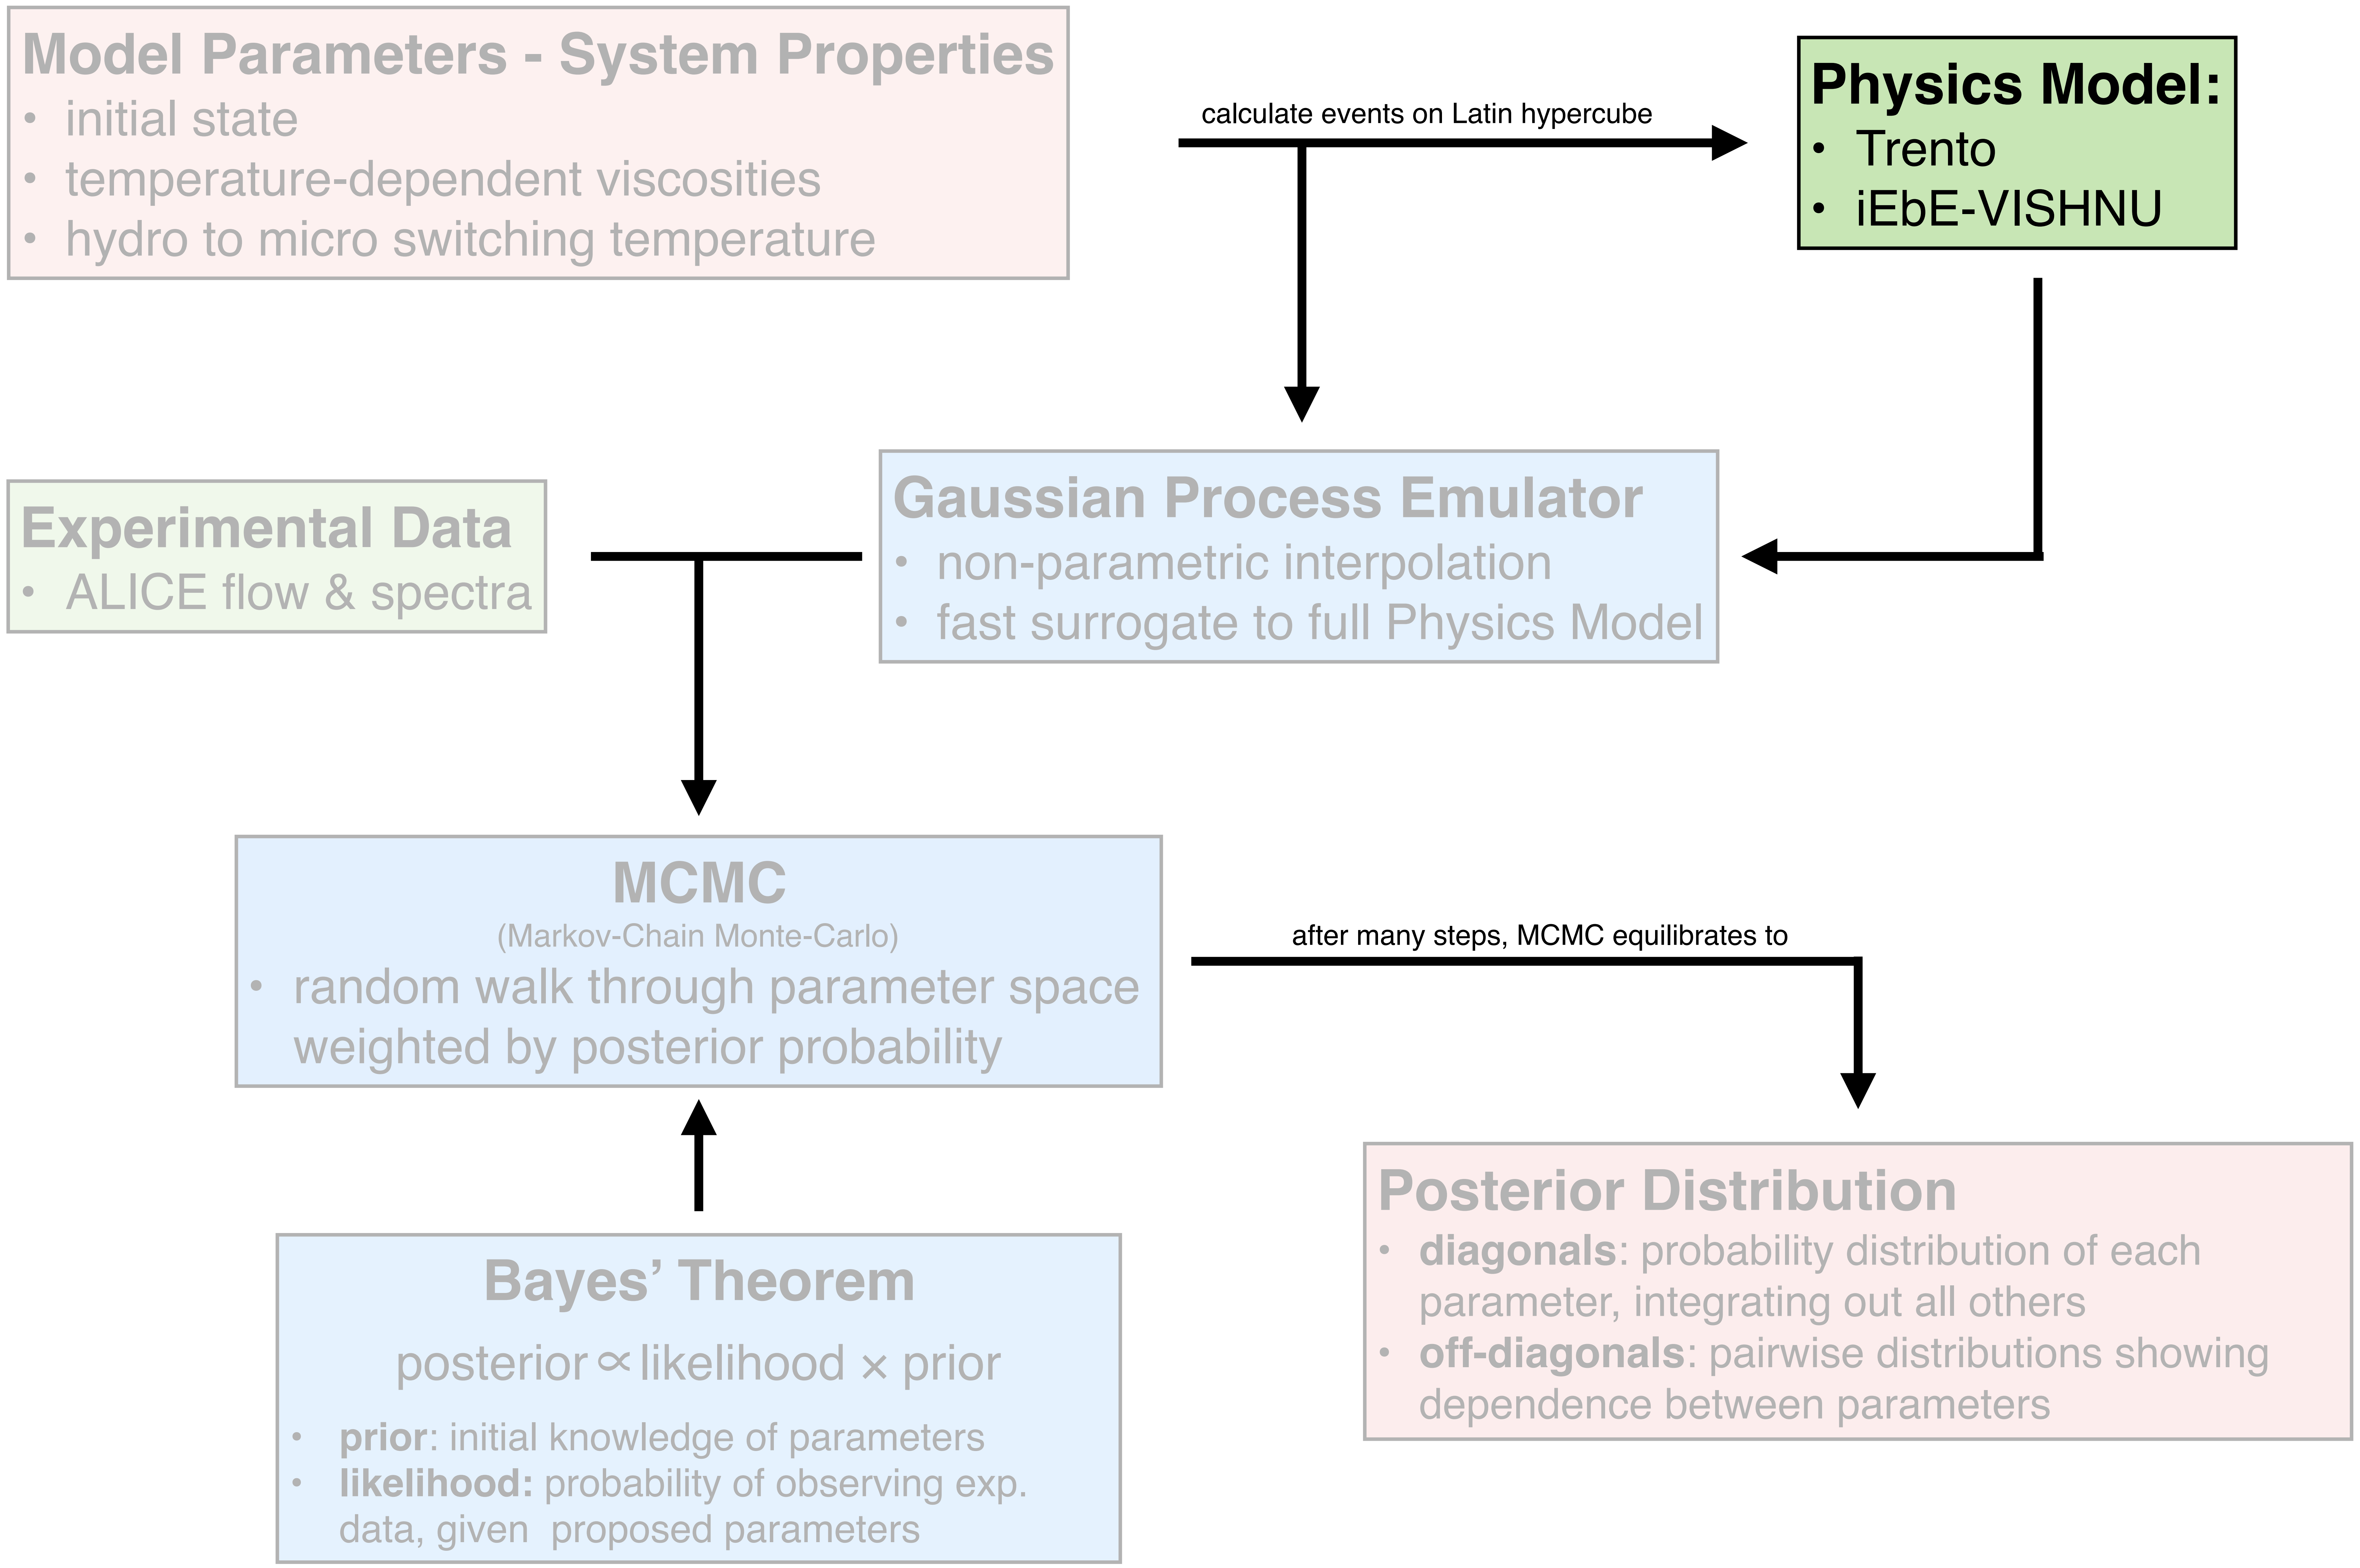


Setup of a Bayesian Statistical Analysis

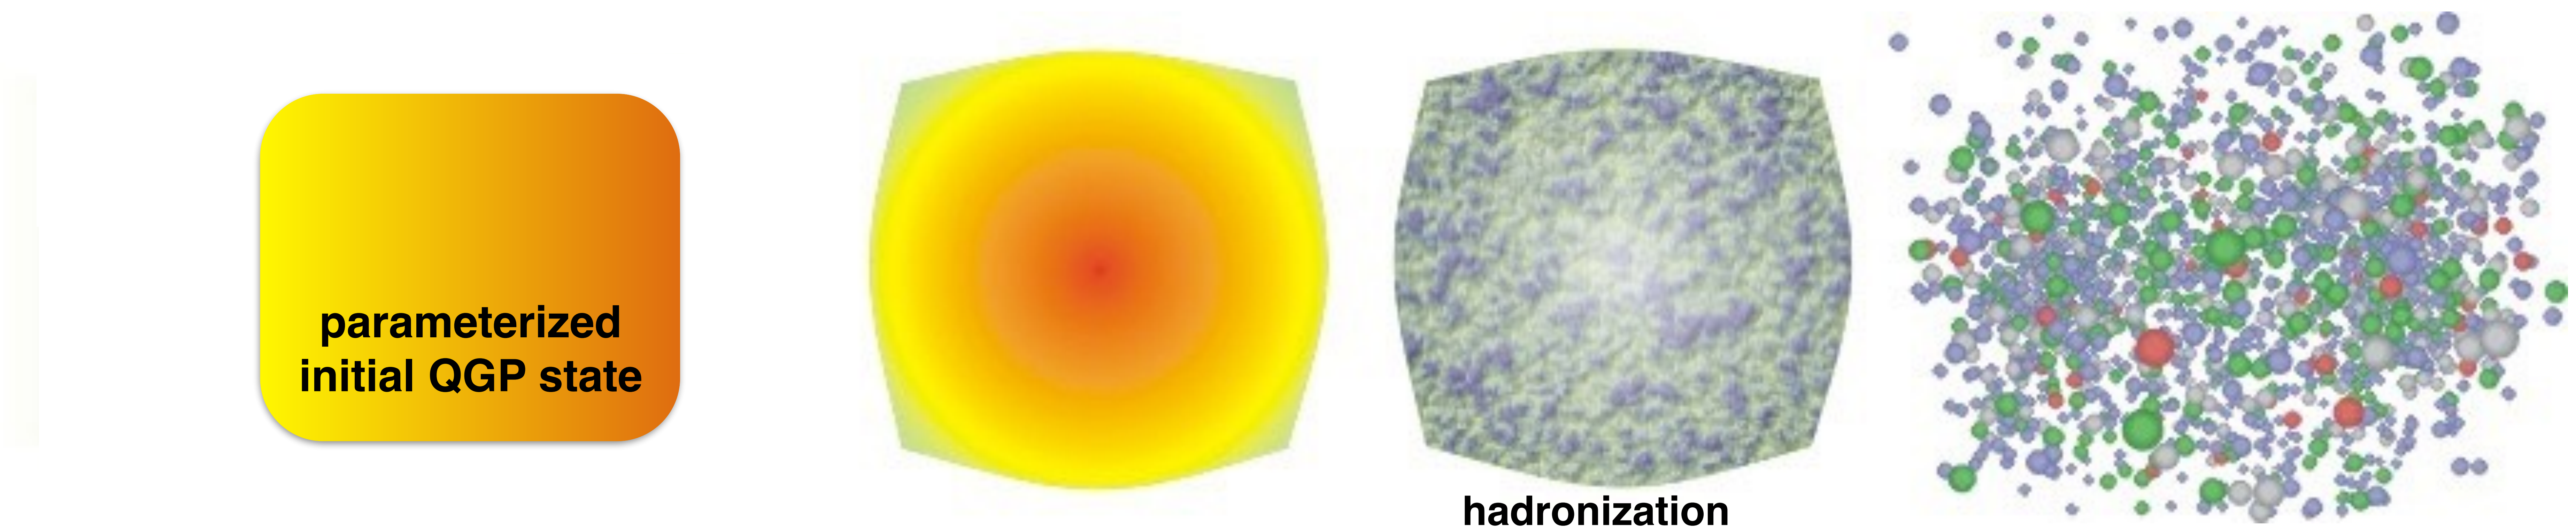


Components of the Bayesian Analysis

Methodology

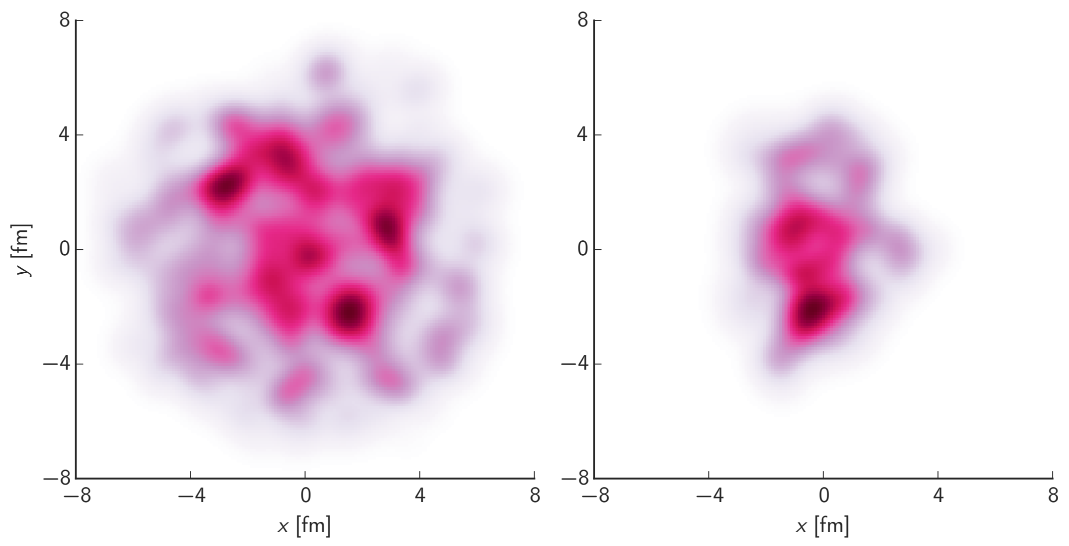


Physics Model: Trento + iEbE-VISHNU



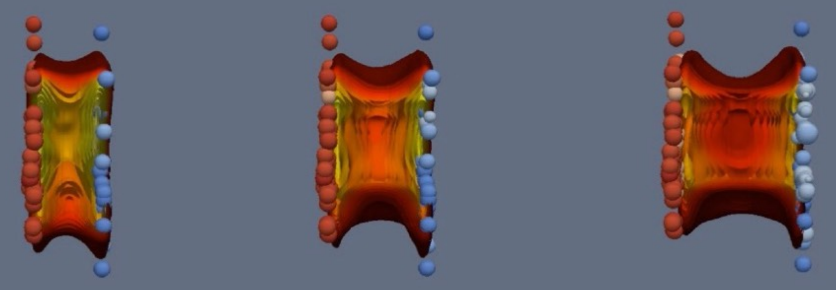
Trento:

- parameterized initial condition model based on phenomenological concepts for entropy deposition to a QGP



iEbE-VISHnew:

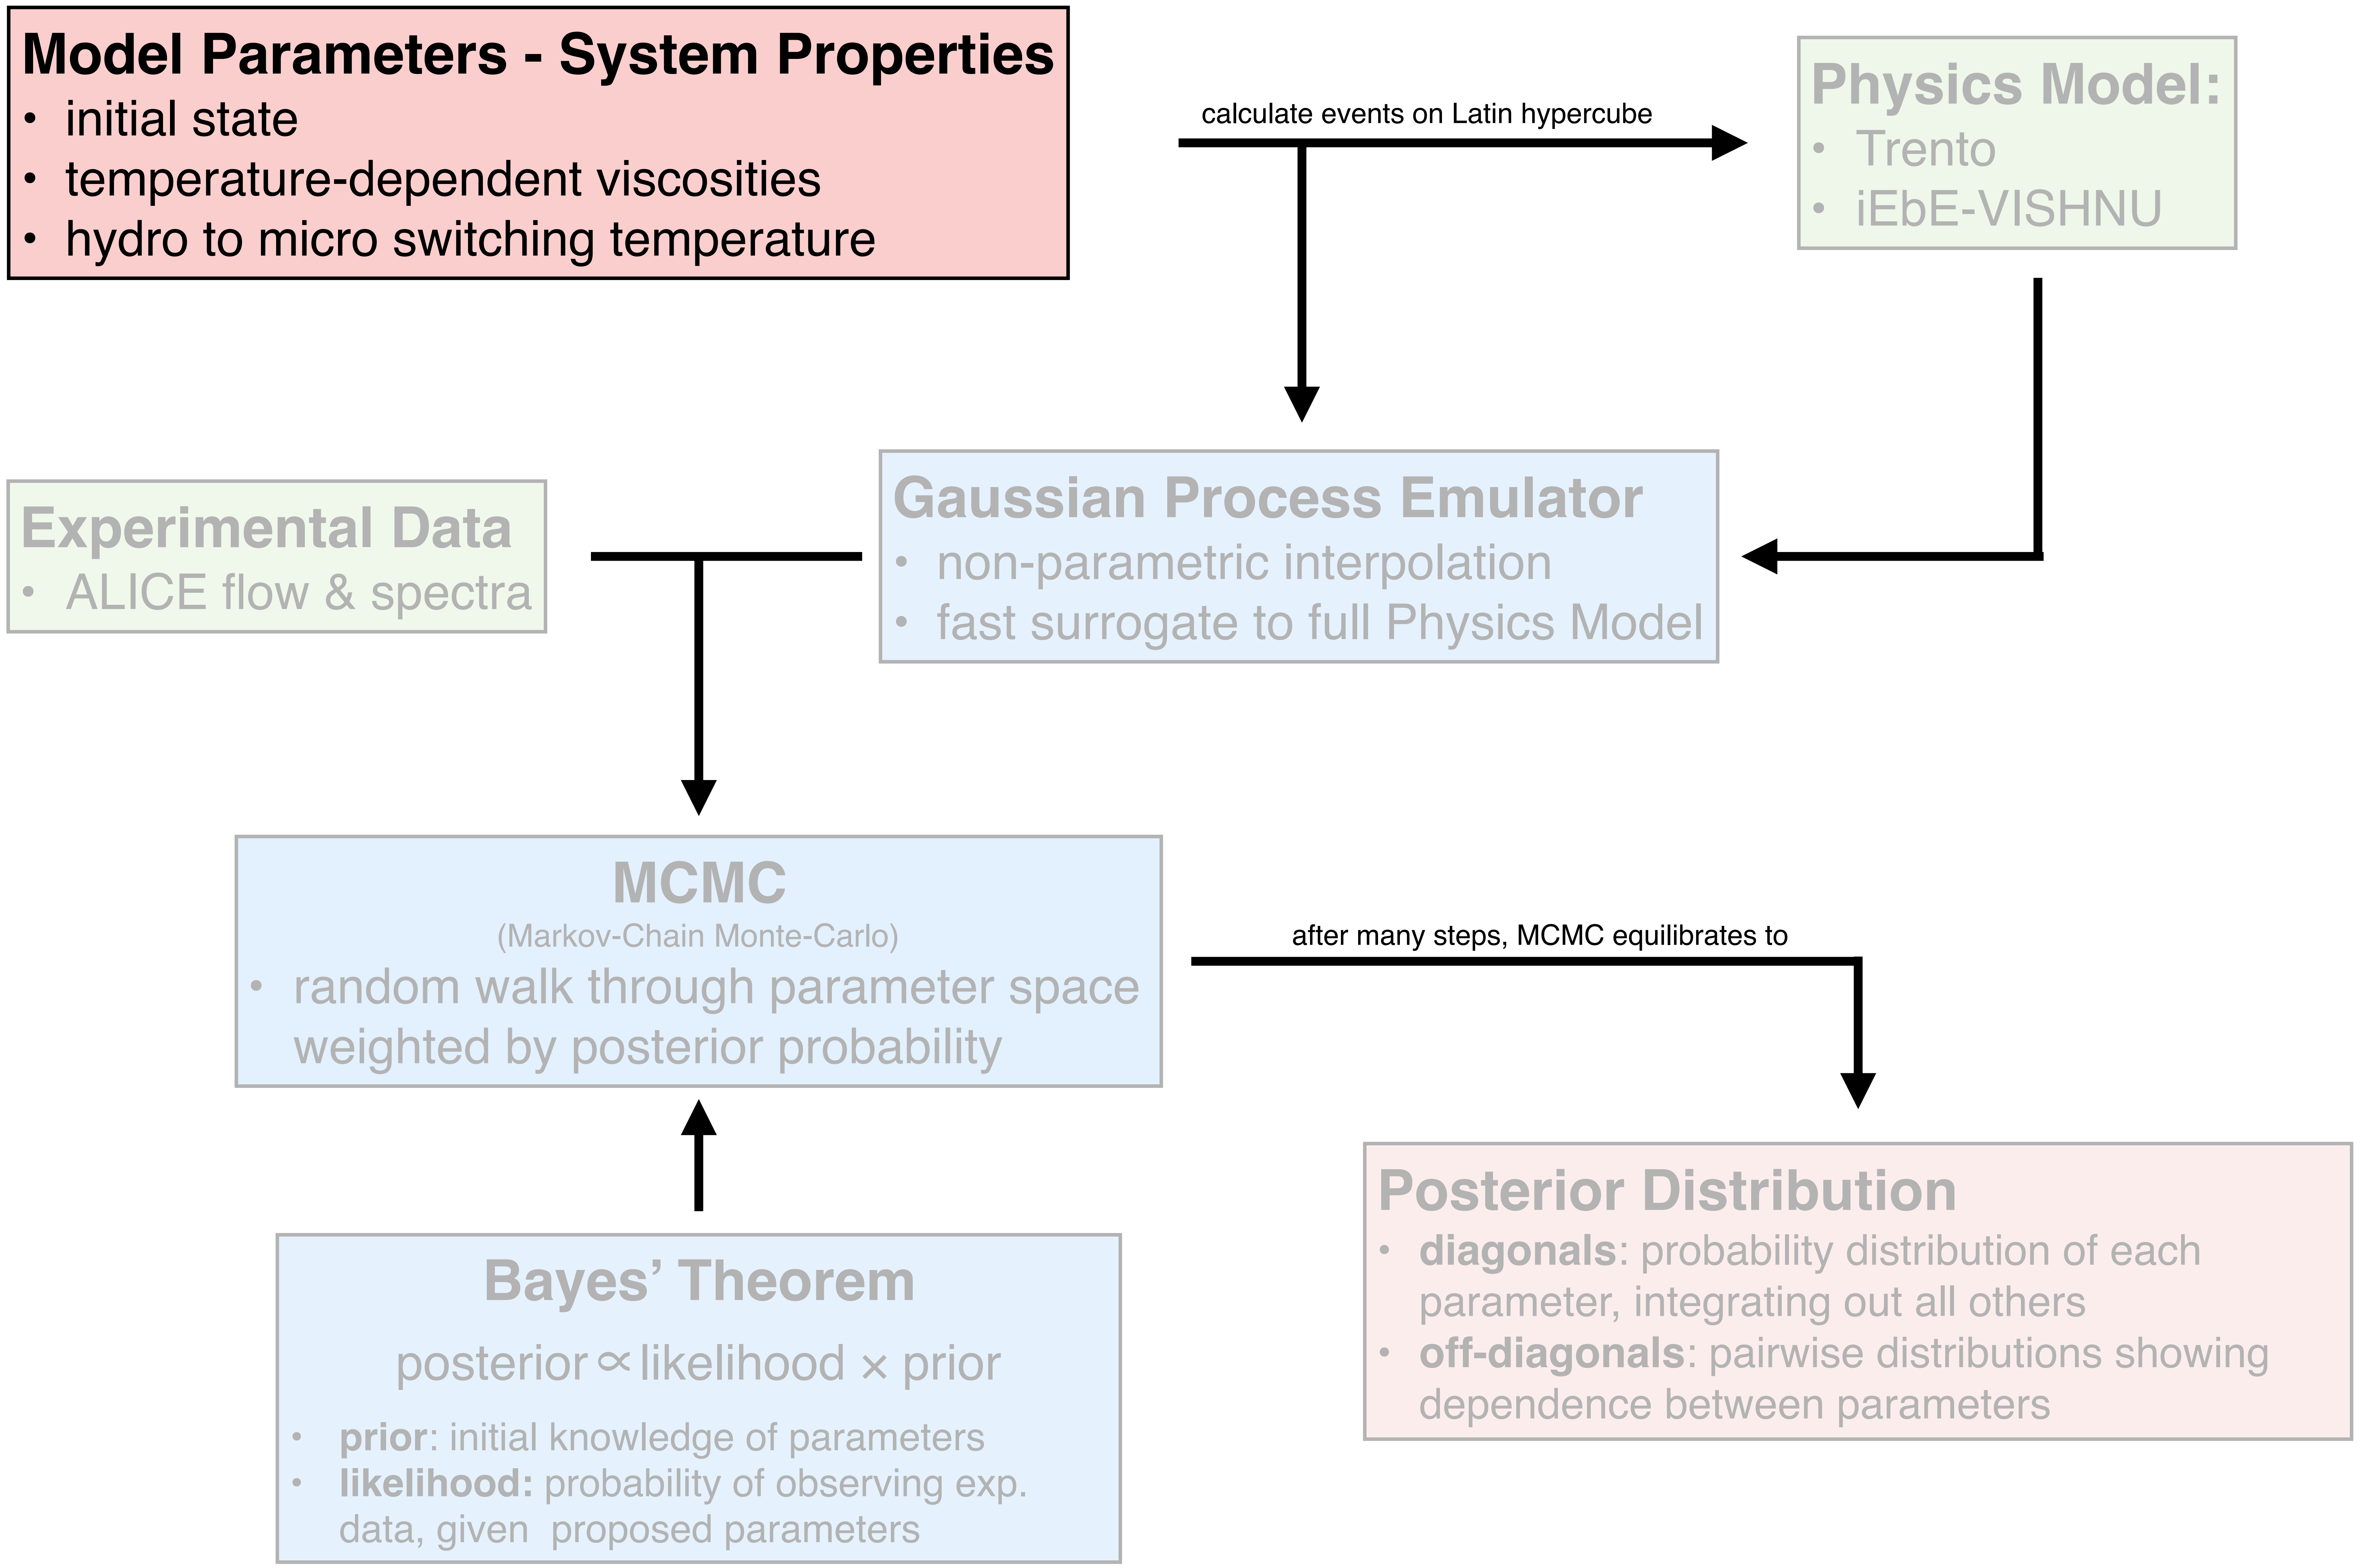
- EbE 2+1D viscous RFD
- describes QGP dynamics & hadronization
- EoS from Lattice QCD
- temperature-dependent shear and bulk viscosity as input



UrQMD:

- non-equilibrium evolution of an interacting hadron gas
- hadron gas shear & bulk viscosities are implicitly contained in calculation

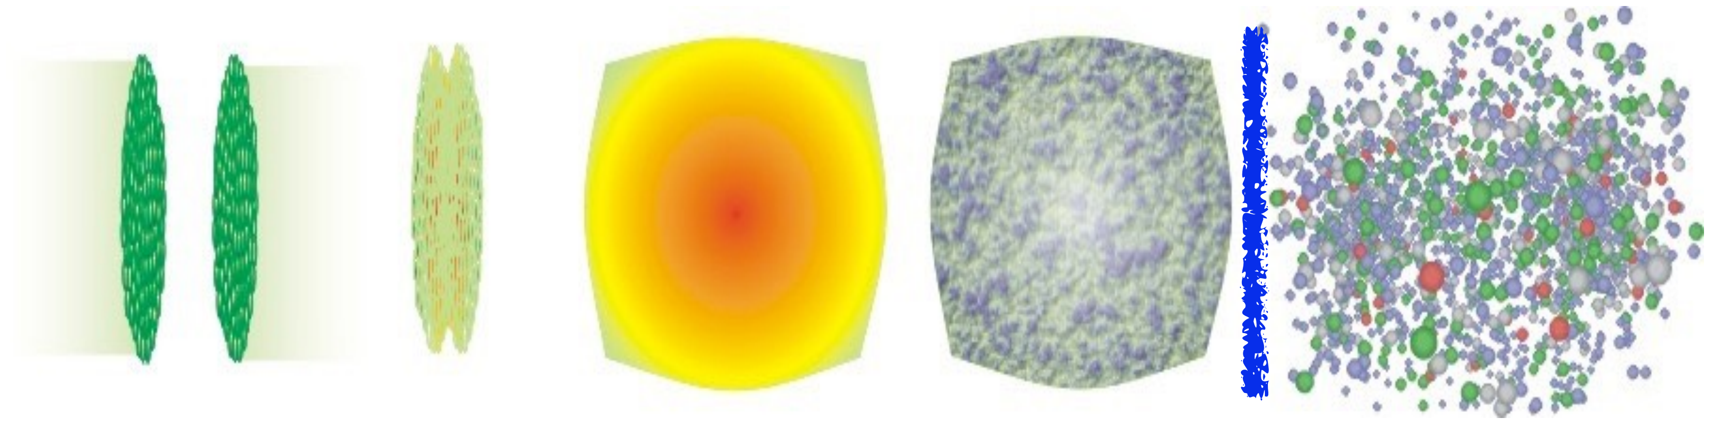
Methodology



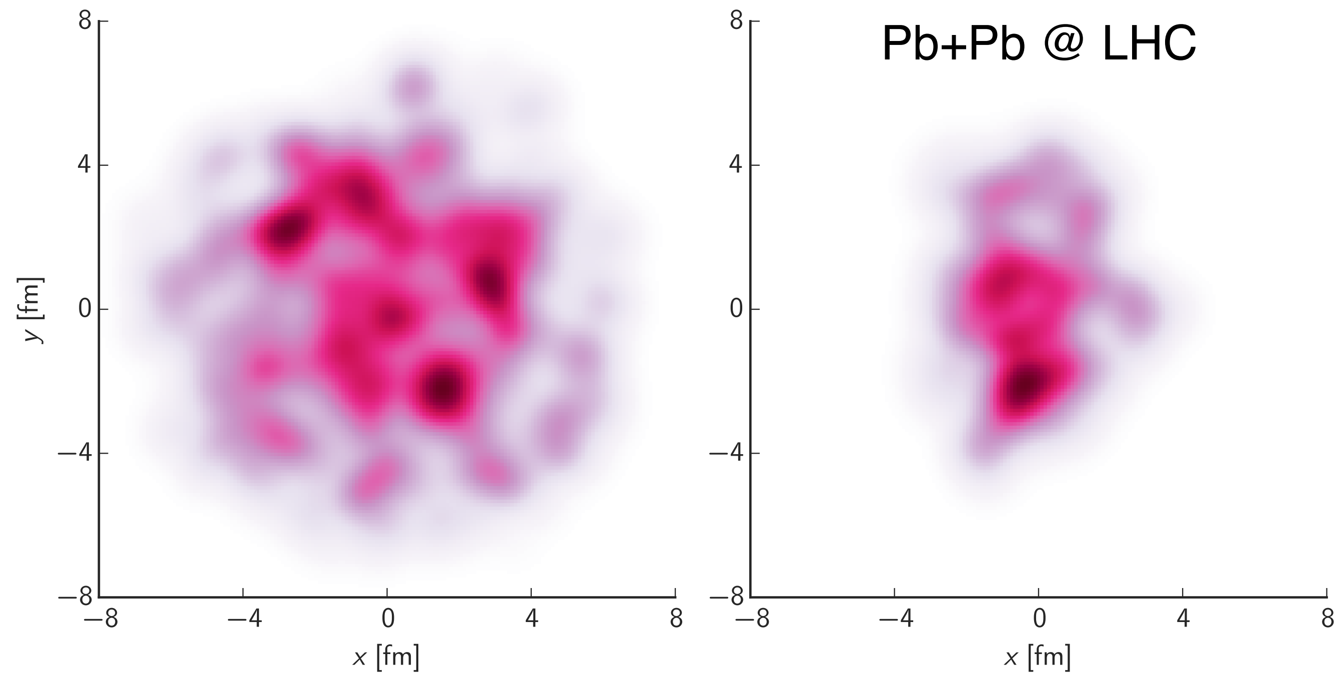
Calibration Parameters

- the calibration parameters are the model parameters that codify the physical properties of the system that we wish to characterize with the analysis

- hydro to micro switching temperature T_{sw}



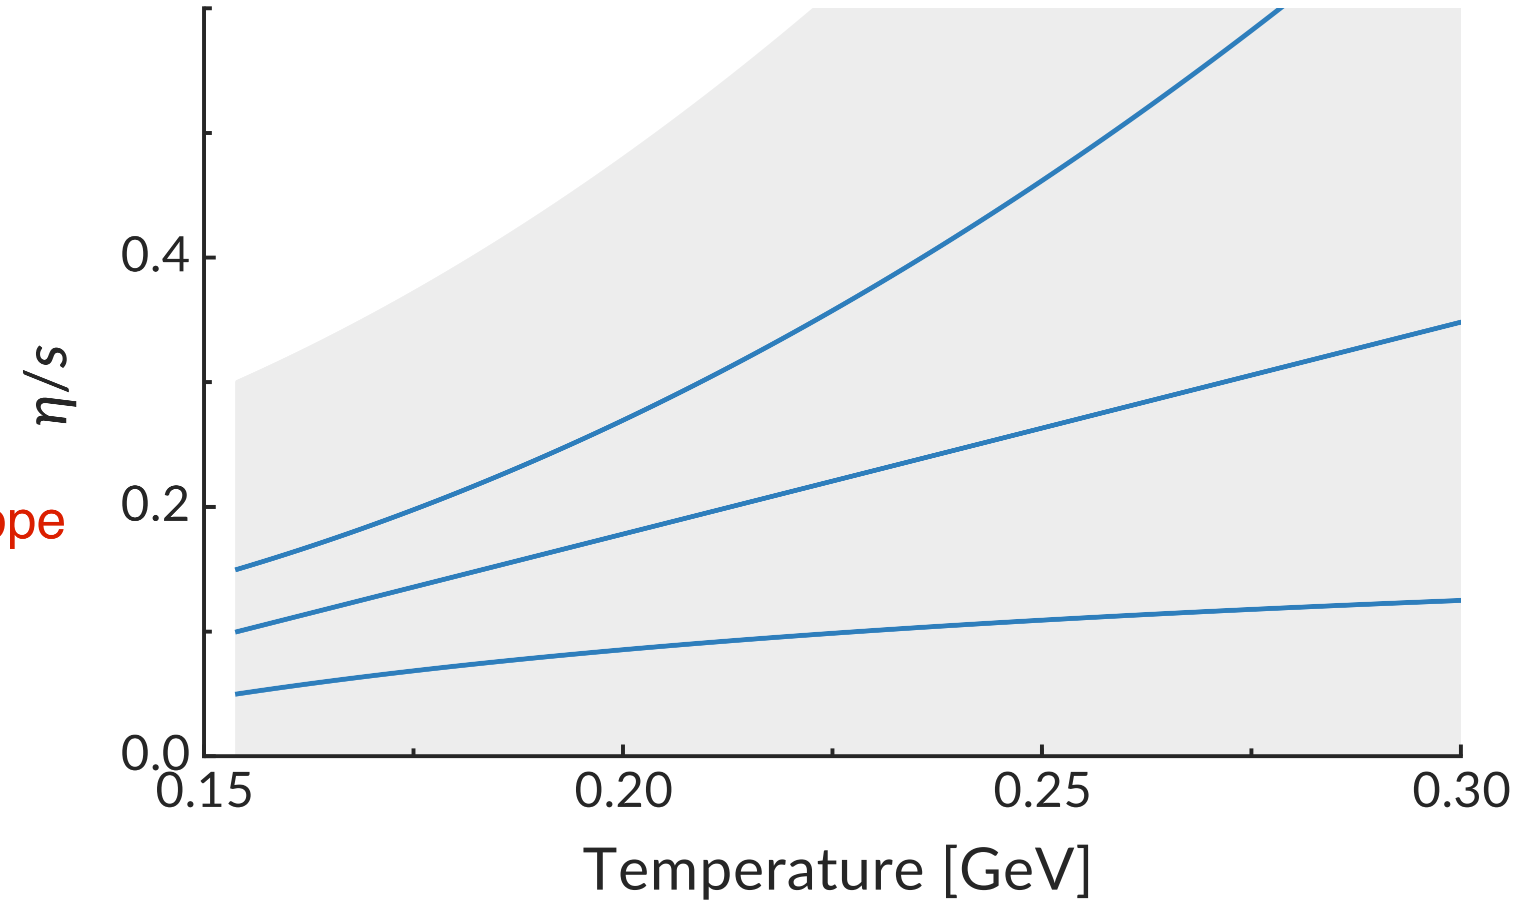
Trento initial condition:
- p: attenuation parameter - entropy deposition
- k: governs fluctuation in nuclear thickness
- w: Gaussian nucleon width



temperature dependent shear viscosity:

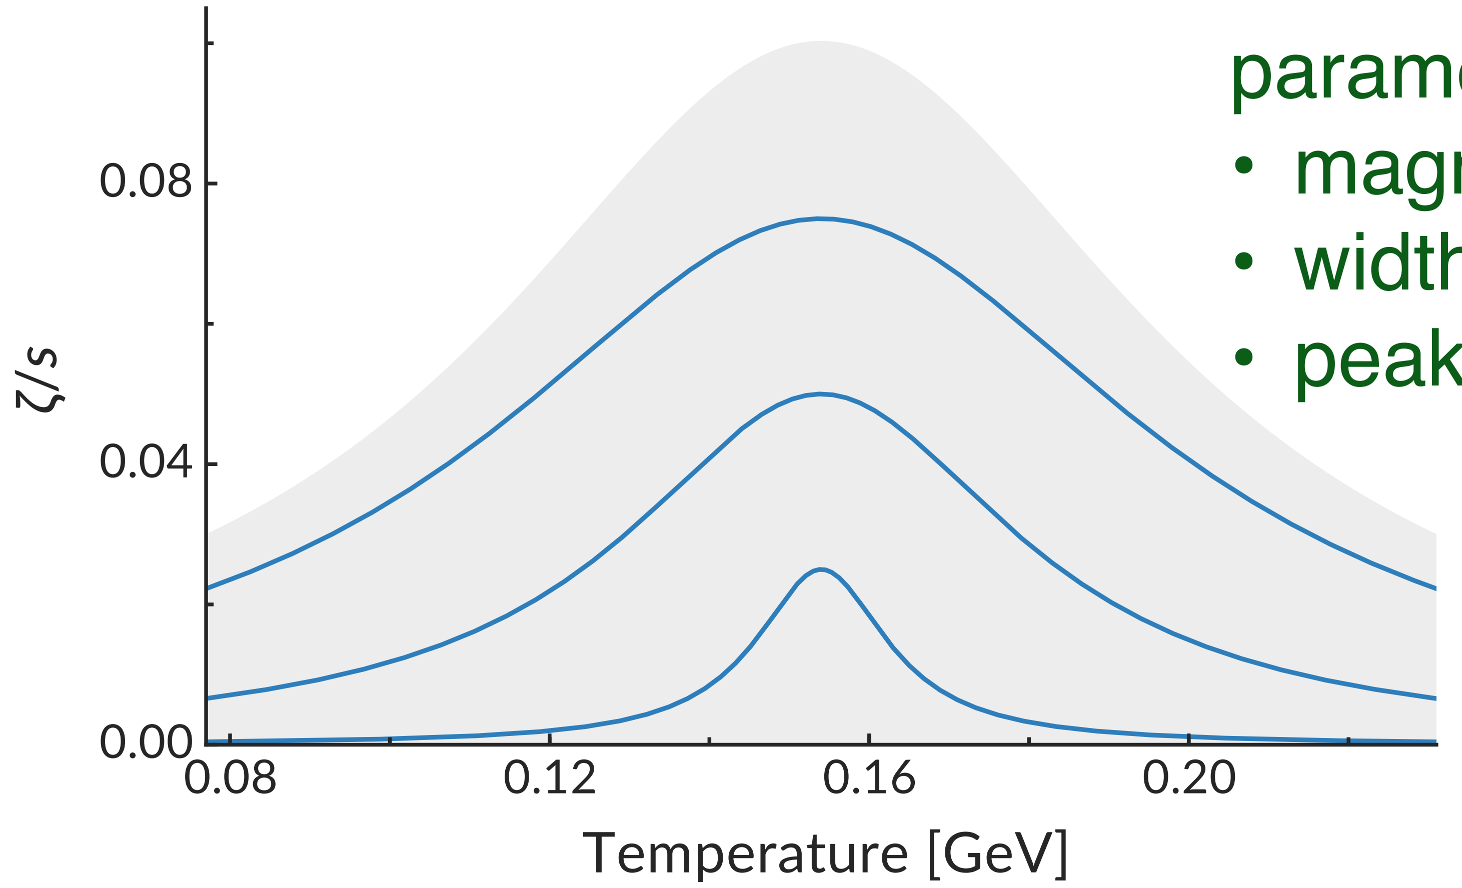
$$\eta/s(T) = (\eta/s)_{min} + (\eta/s)_{slope} \times (T-T_C)\times(T/T_C)^{\beta}$$

parameters:
- intercept: $(\eta/s)_{min}$ at T_C
- slope: $(\eta/s)_{slope}$
- curvature: β



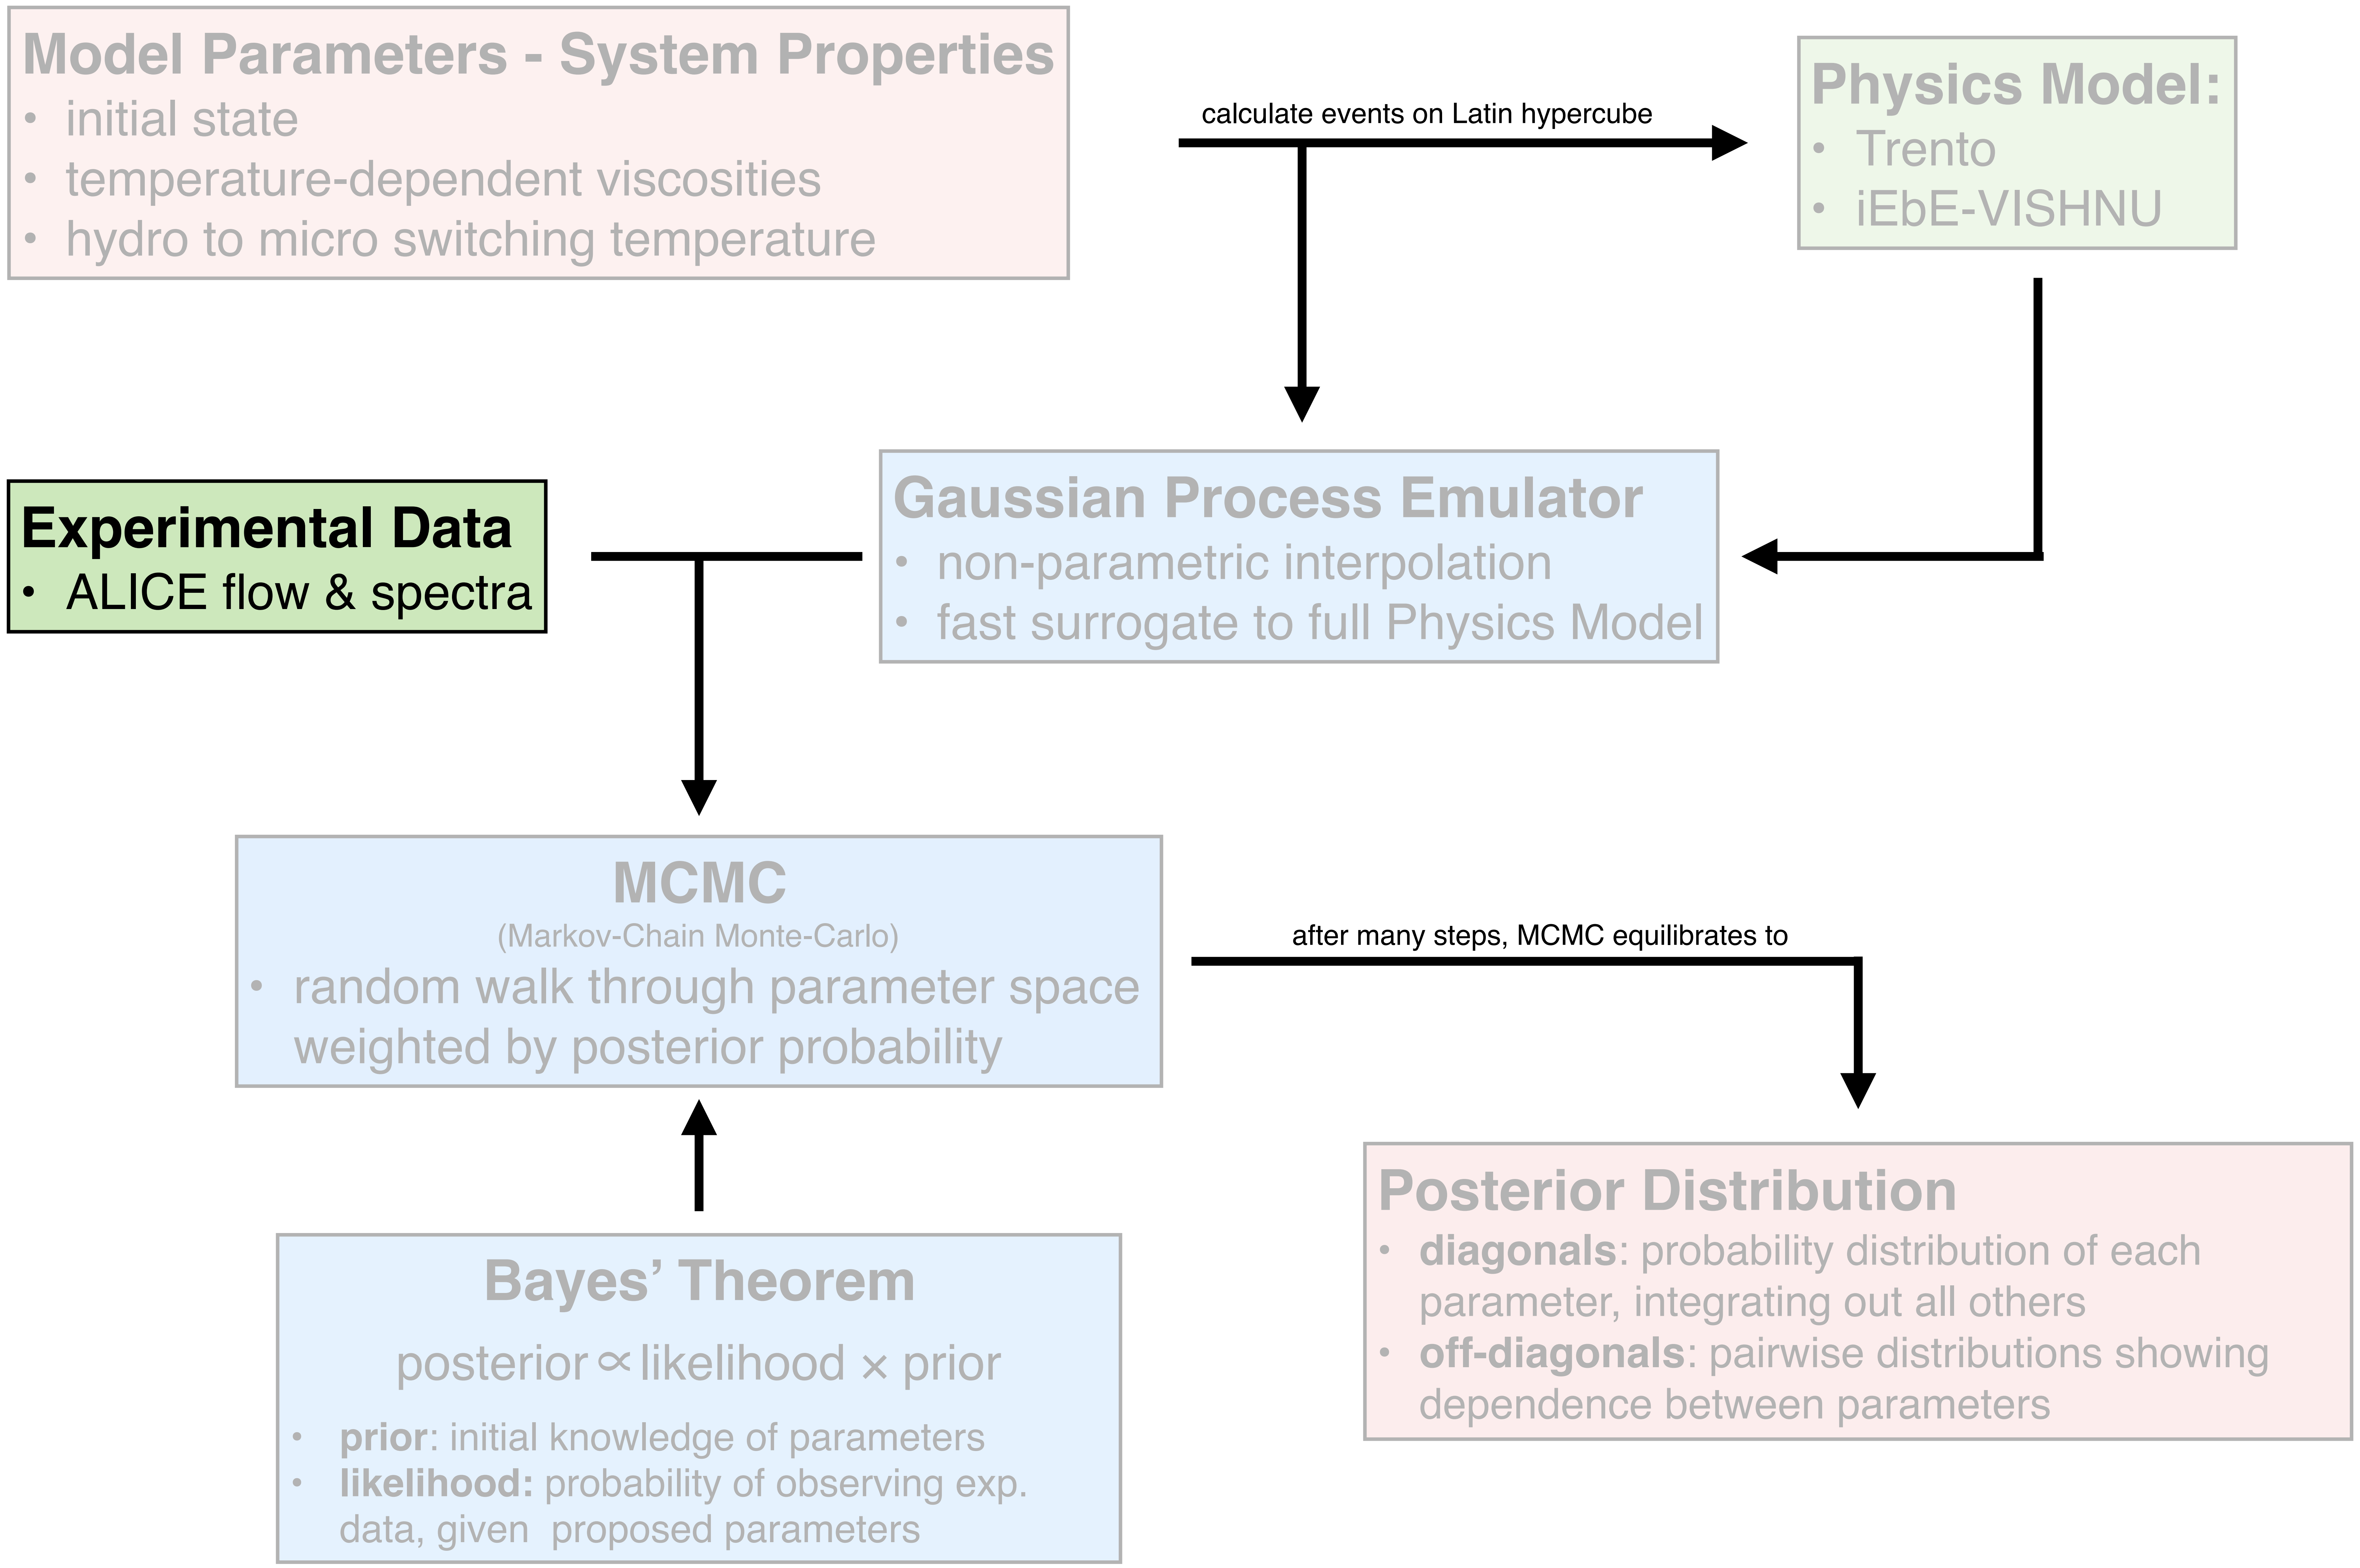
temperature dependent bulk viscosity:

$$\zeta/s(T)=(\zeta/s)_{max} / [1+(T-(\zeta/s)_{peak})^2/\Gamma^2]$$



parameters:
- magnitude $(\zeta/s)_{max}$
- width: Γ
- peak position: $(\zeta/s)_{peak}$

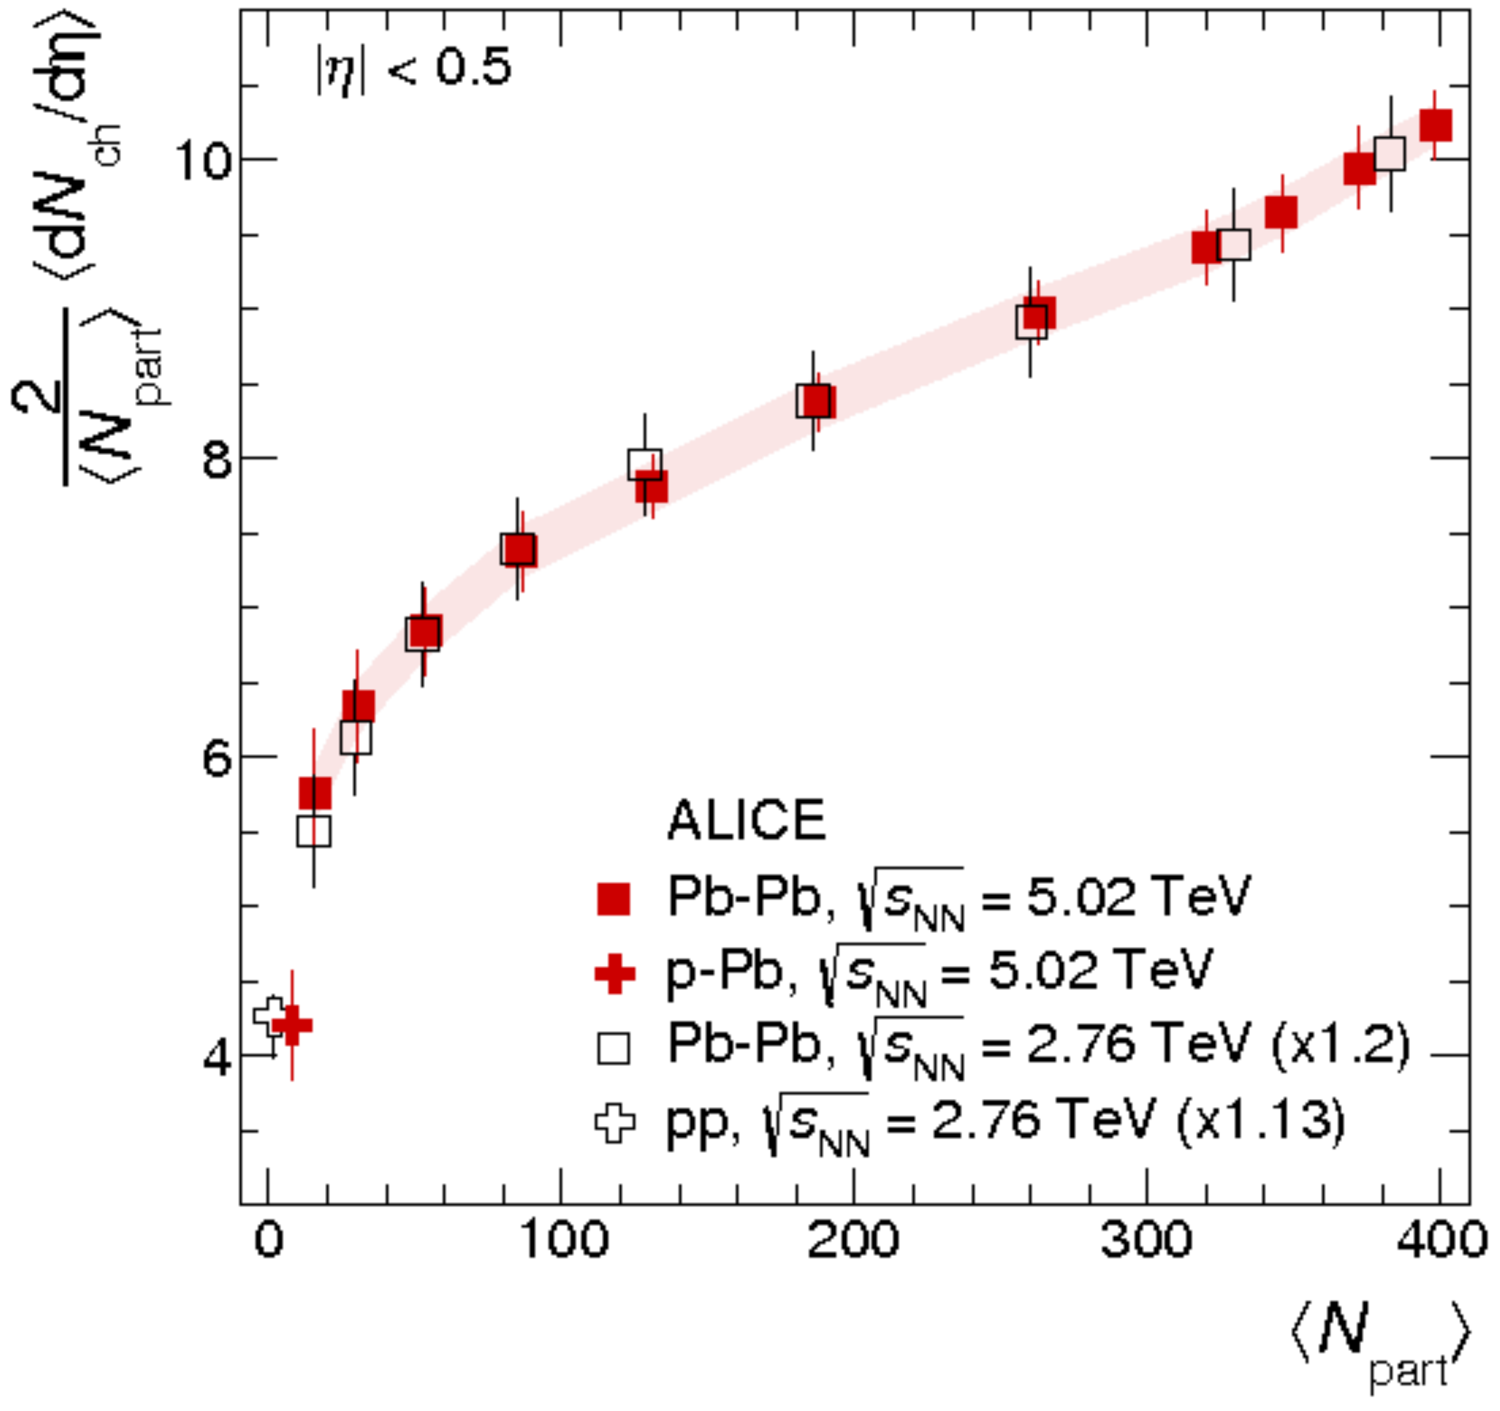
Methodology



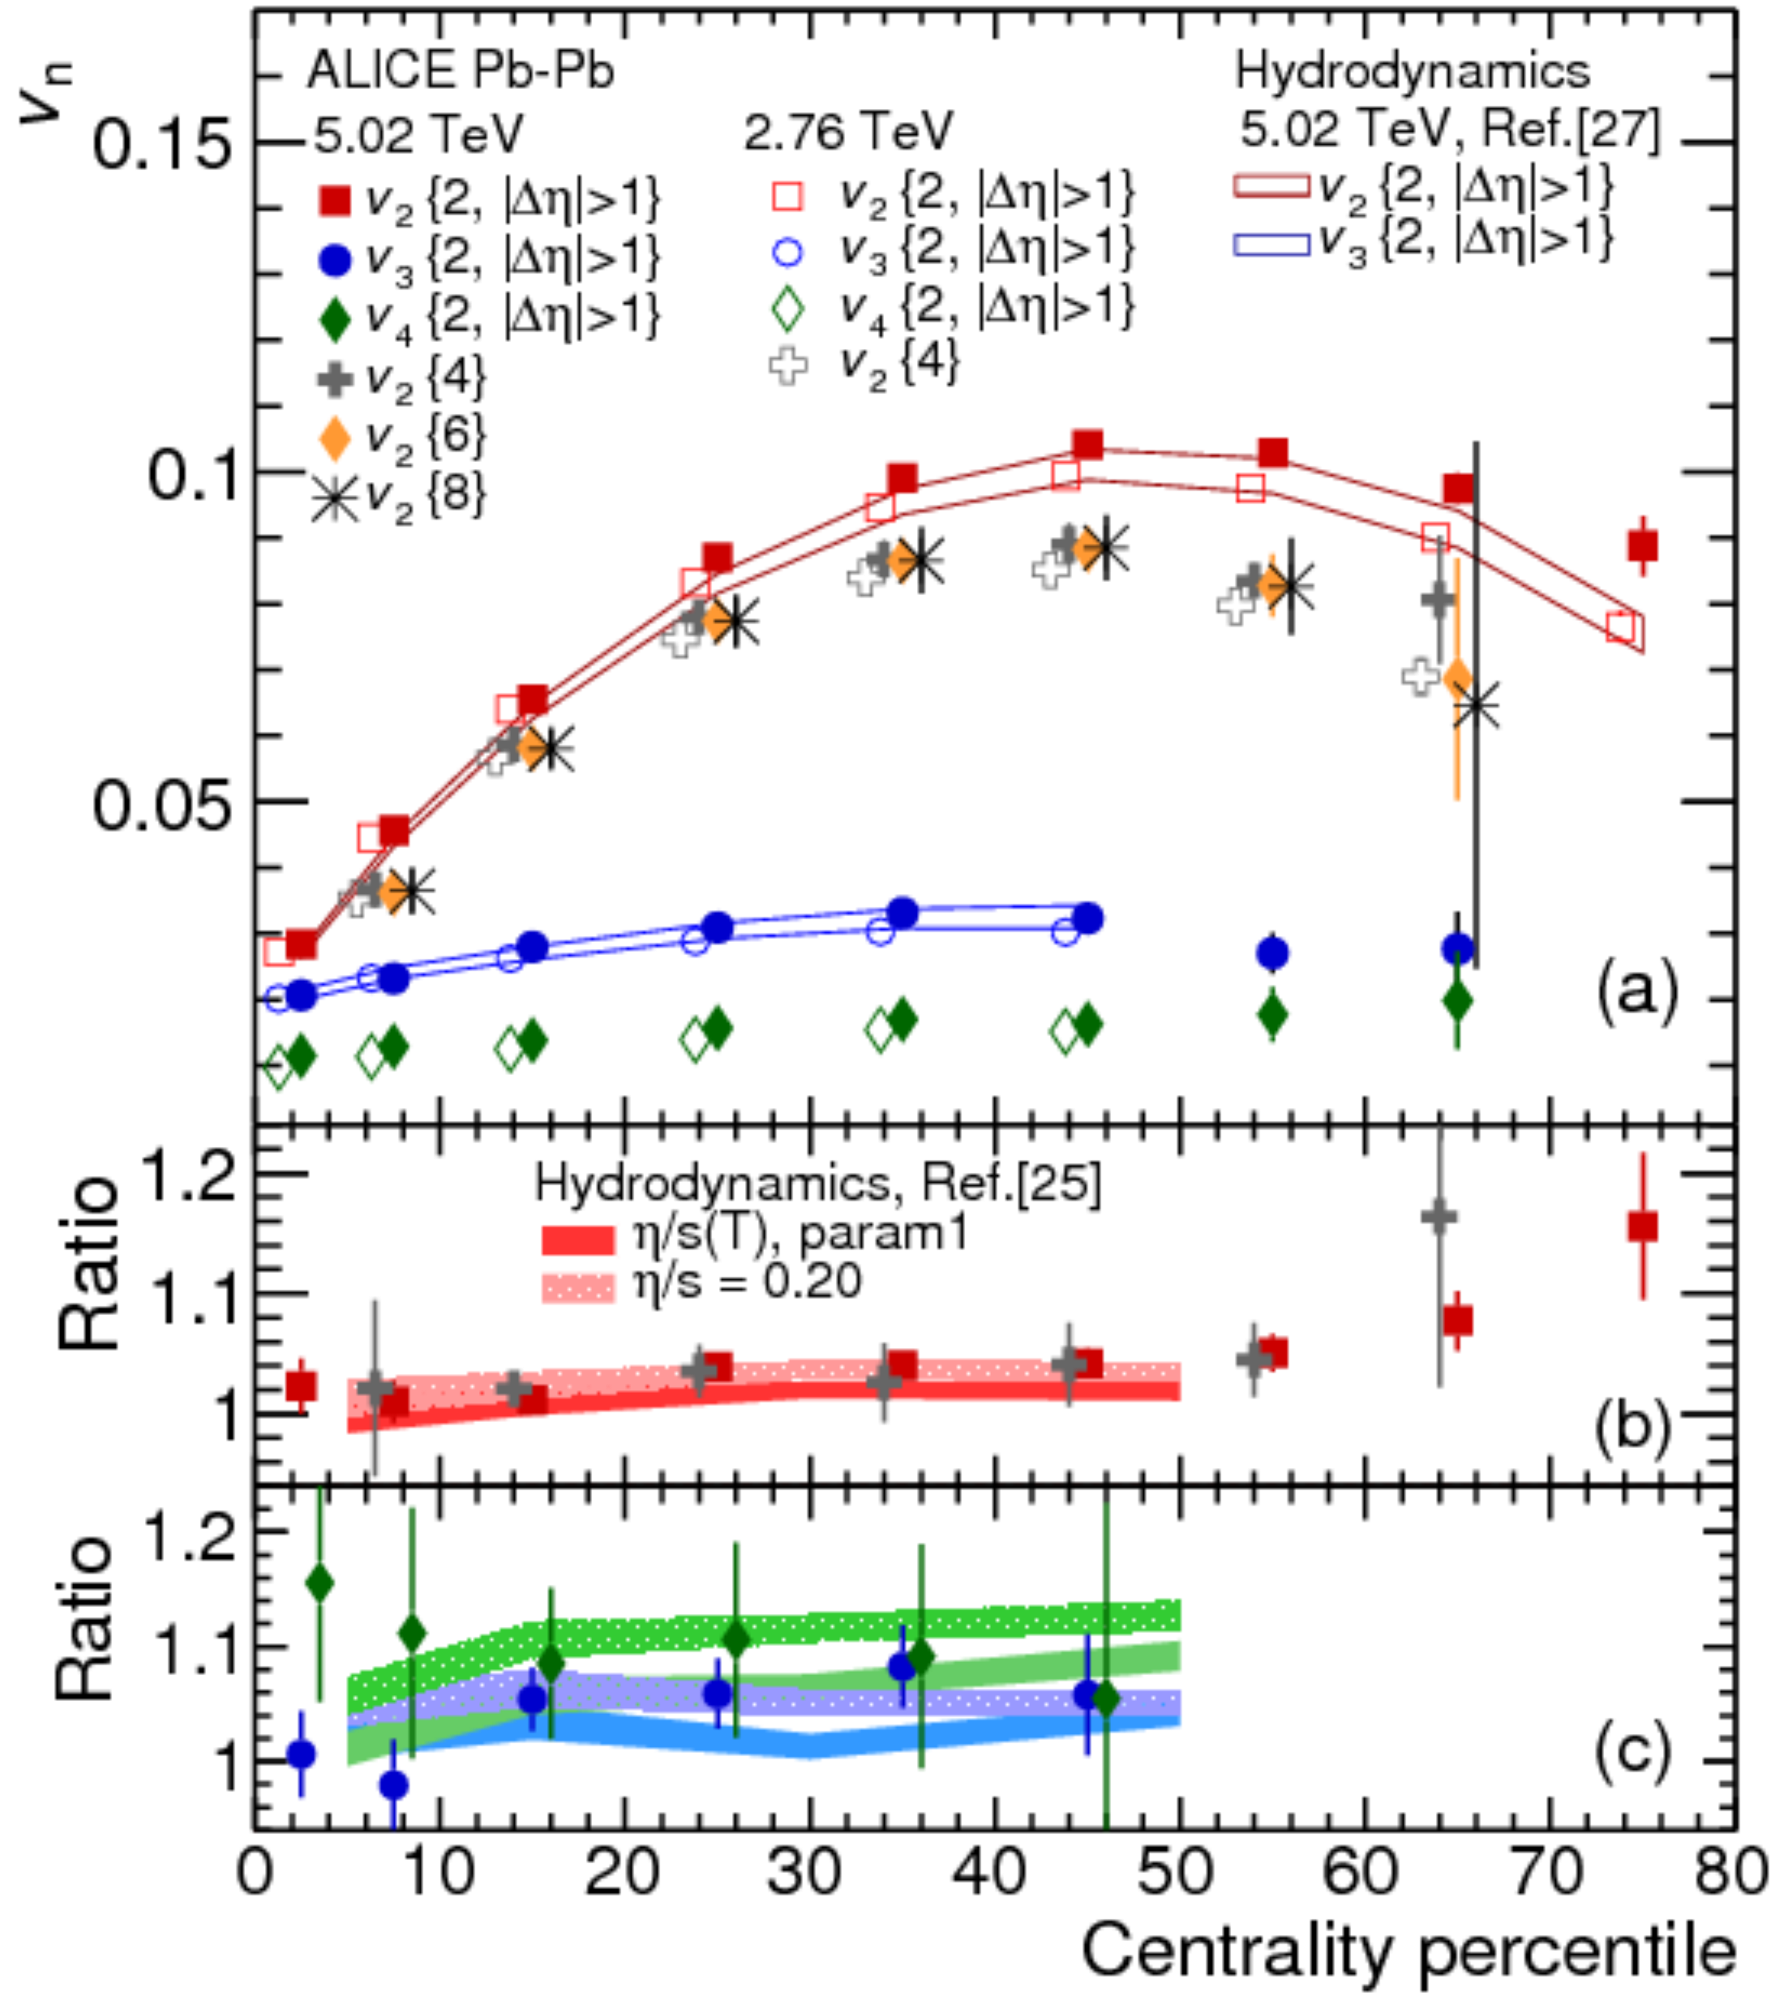
Training Data

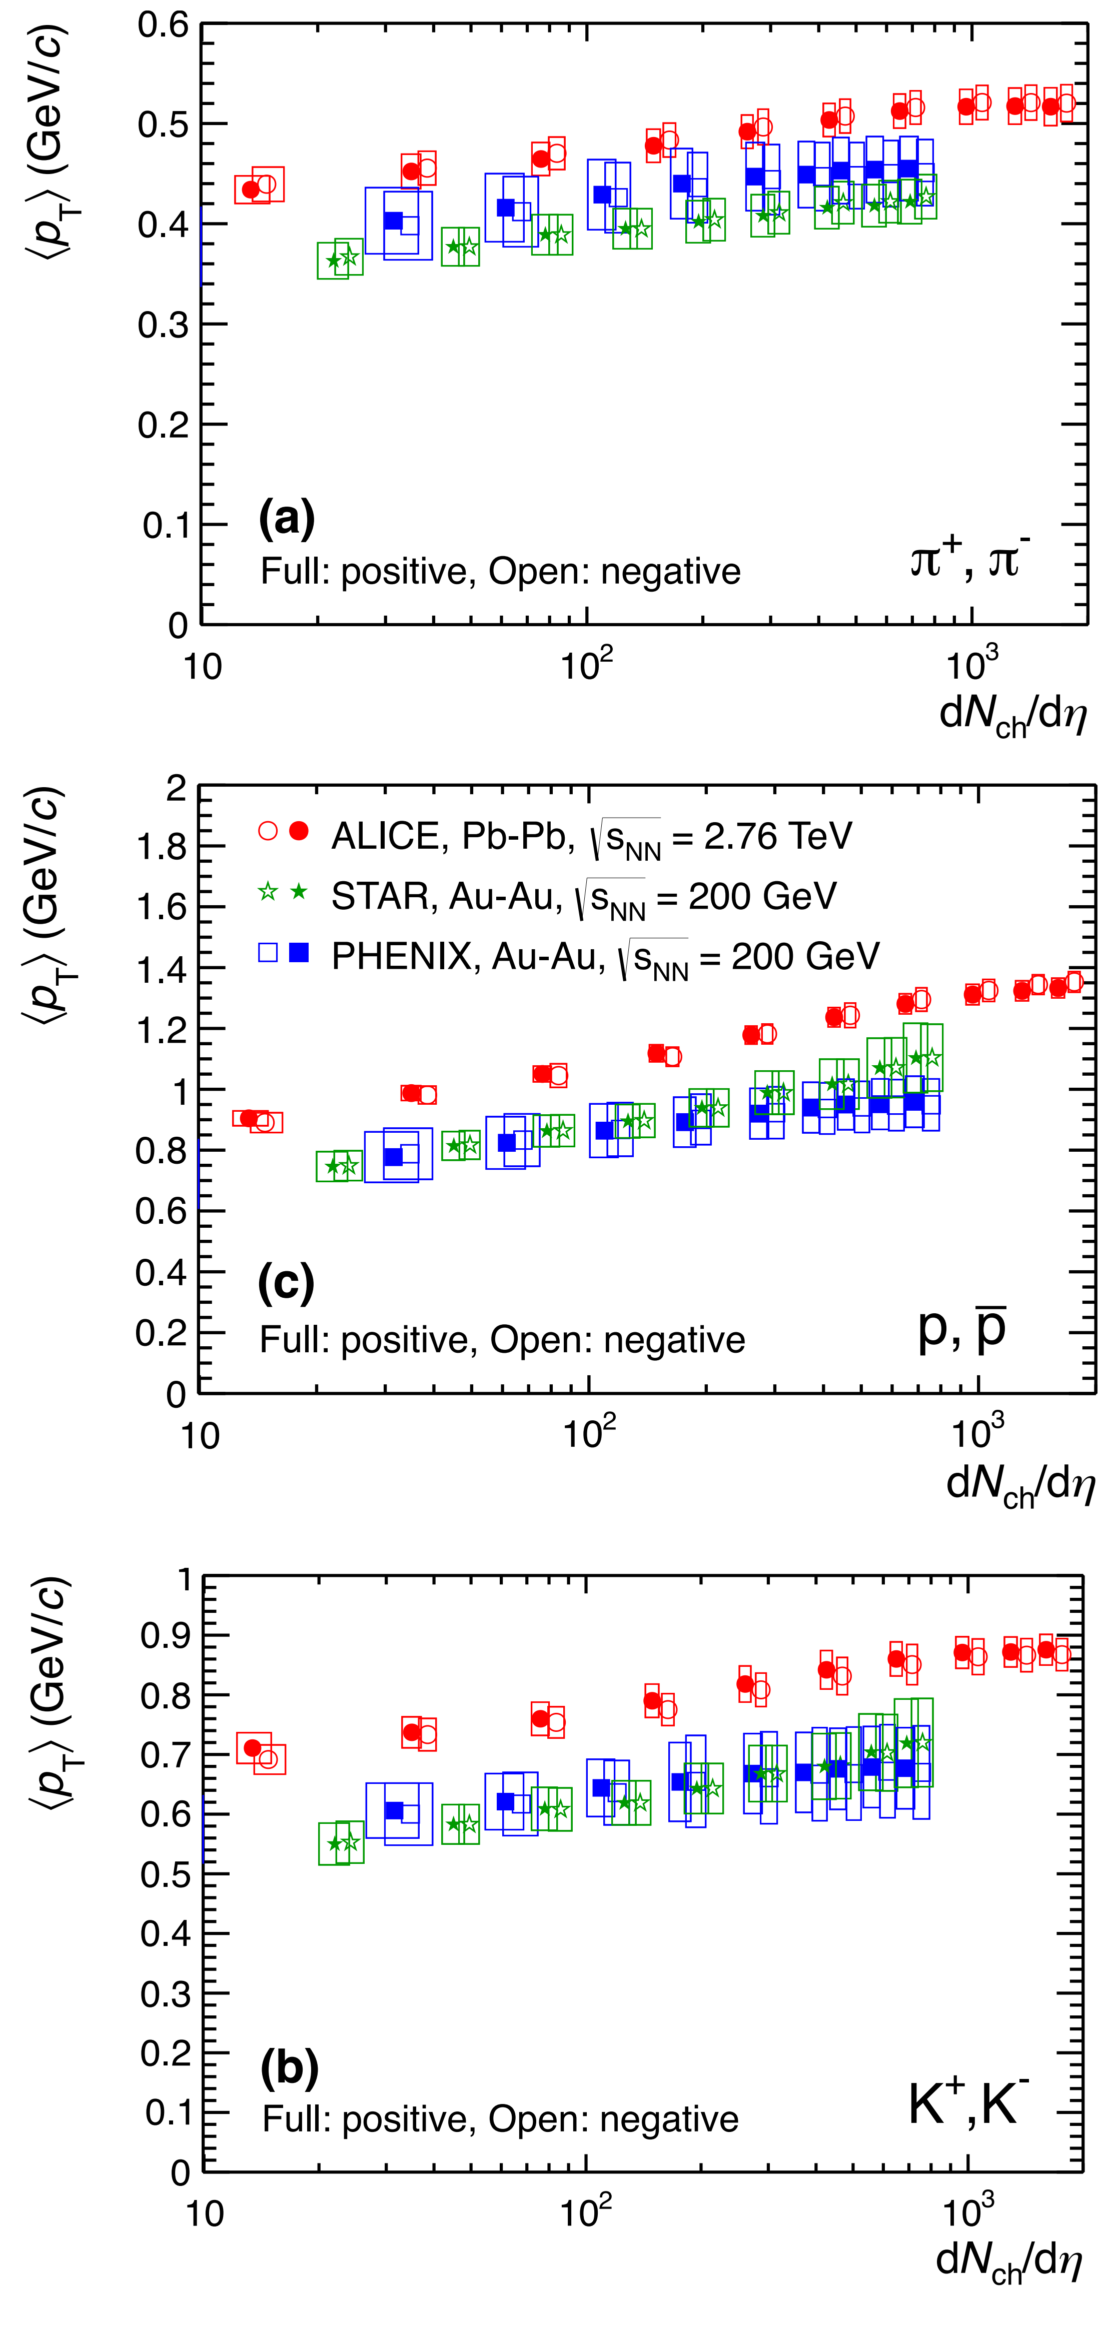
Data:

- ALICE v_2, v_3 & v_4 flow cumulants
- identified & charged particle yields
- identified particle mean p_T
- 2 beam energies:
  2.76 & 5.02 TeV

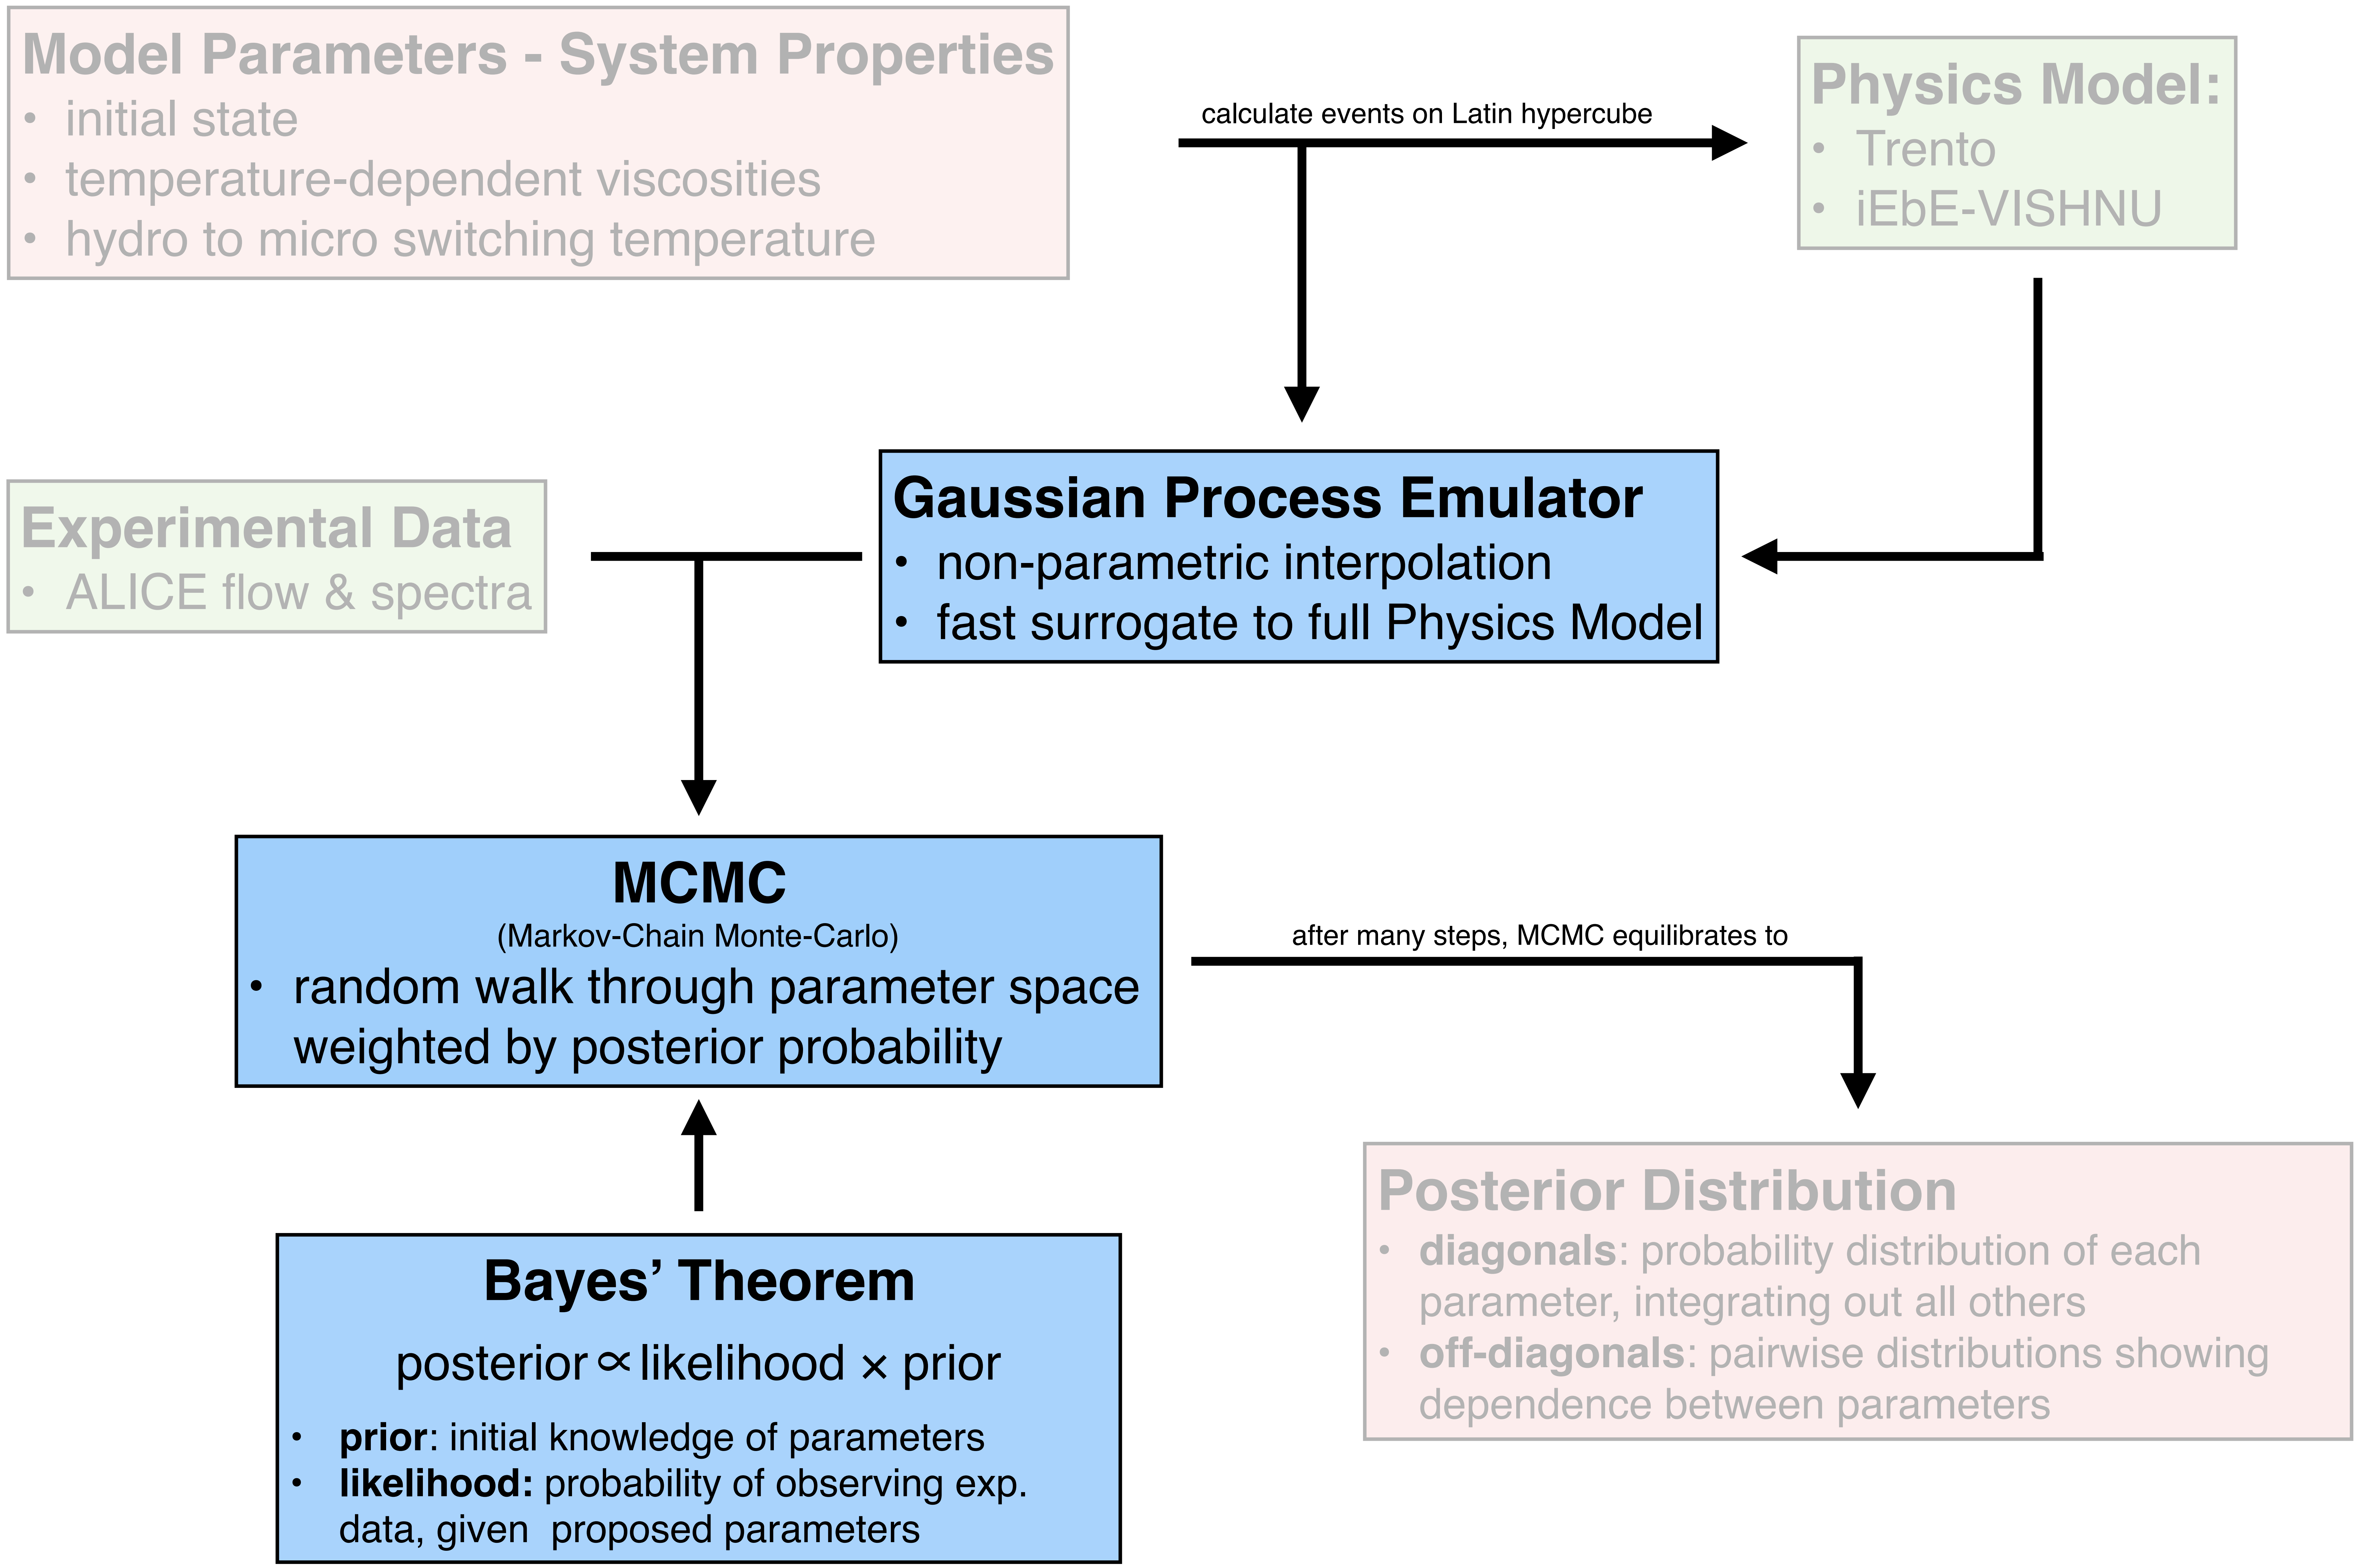


the entire success of the analysis depends on the quality of the exp. data!





Methodology



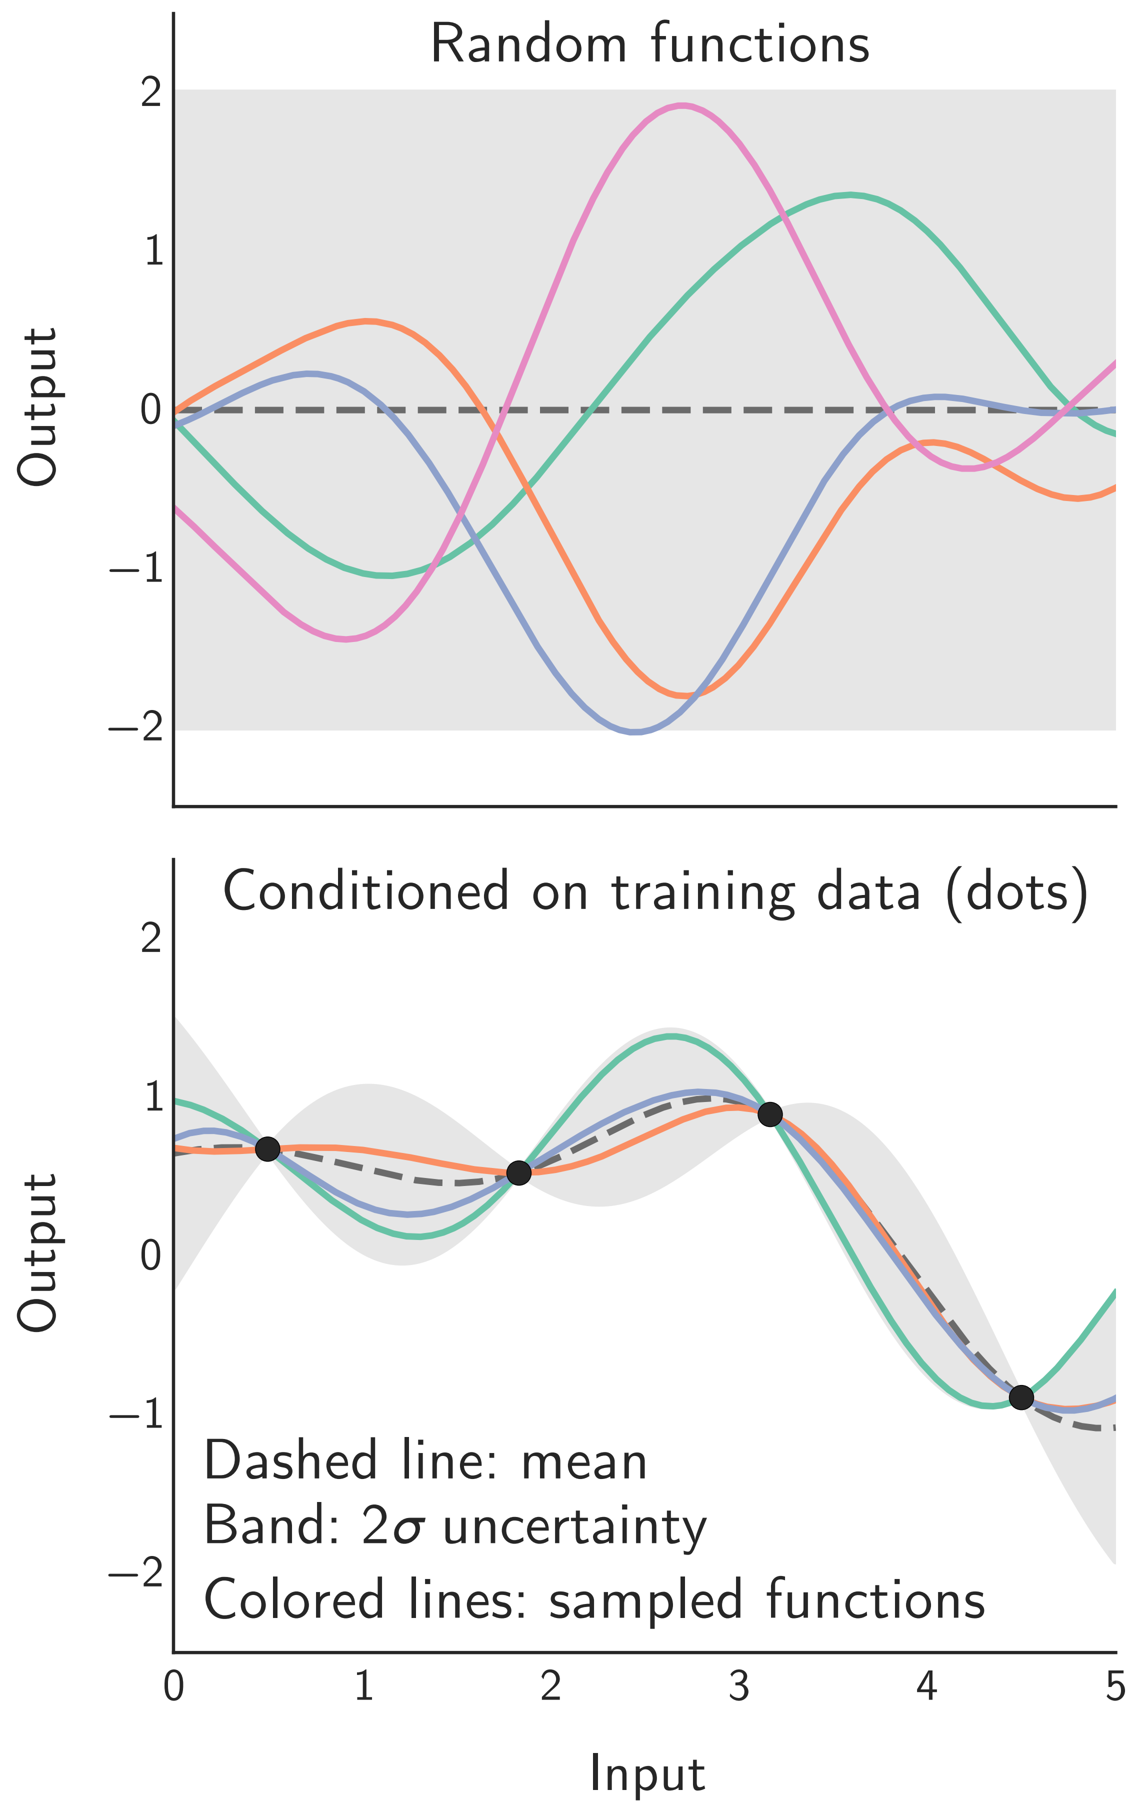
Exploring the Model Parameter-Space

Gaussian process:

- stochastic function:
  maps inputs to normally distributed outputs
- specified by mean and covariance functions

GP as a model emulator:

- non-parametric interpolation of physics model
- predicts probability distributions for model output at any given input value
  - narrow near training points, wide in gaps
- needs to be conditioned on training data (Latin hypercube points)
- fast *surrogate* to actual model



Computer Experiment Design

Latin hypercube:

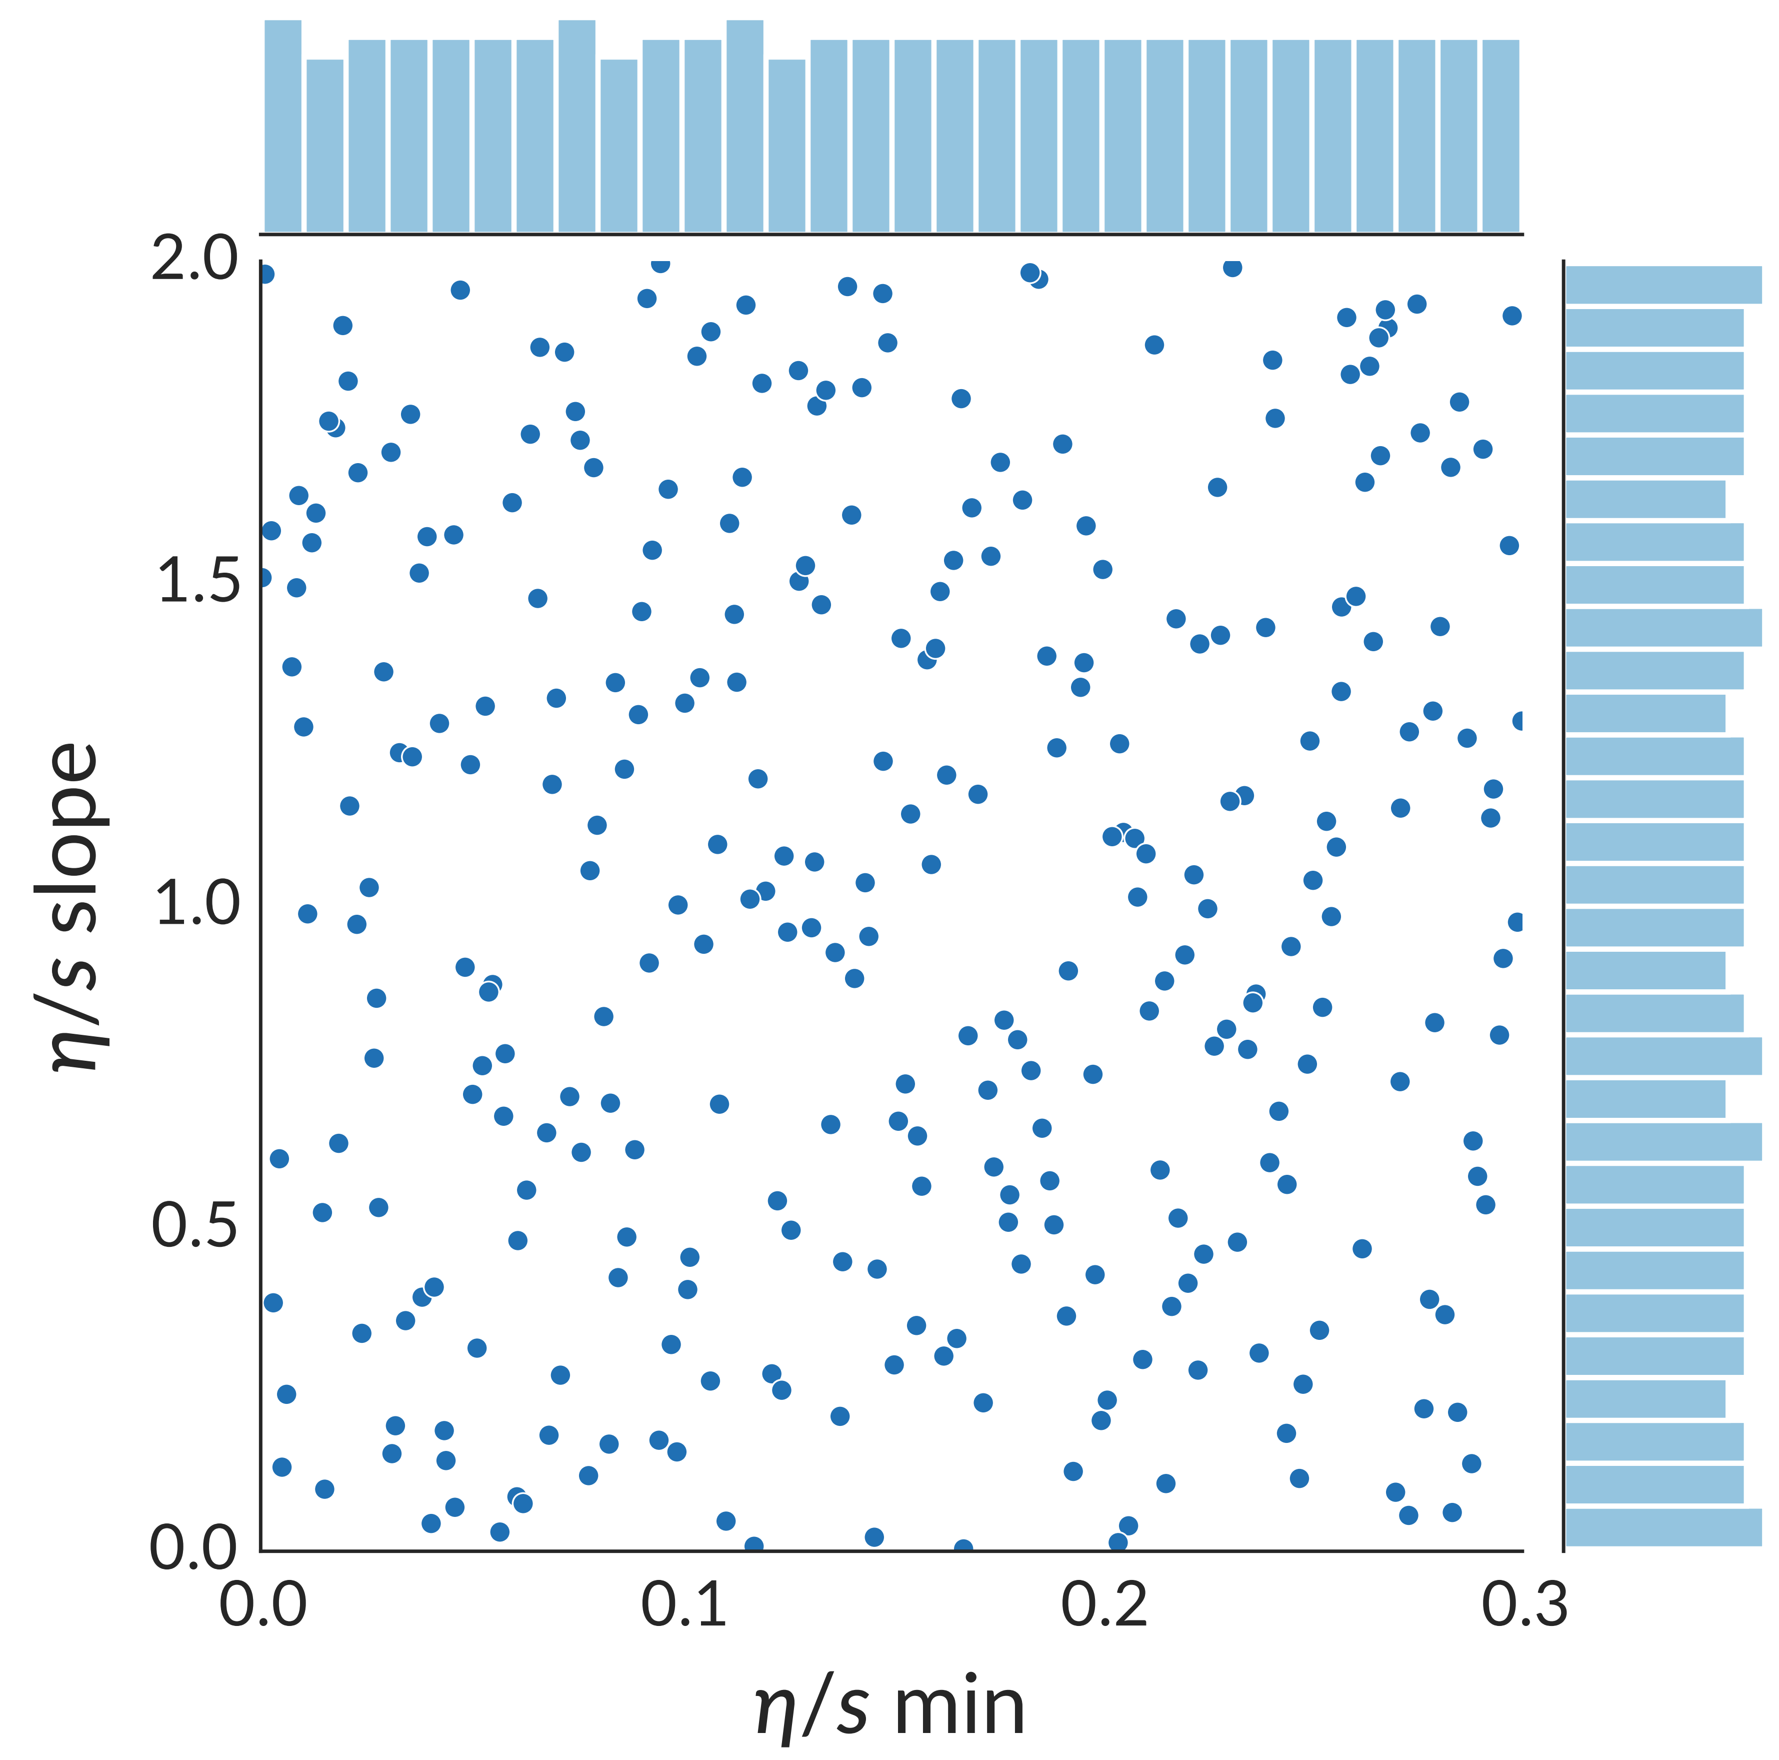
- algorithm for generating semi-randomized, space-filling points (here: maximin Latin hypercube)
- avoids large gaps and tight clusters
- all parameters varied simultaneously
- needs only *m≥10n* points, with
  n: number of model parameters

this design:

- n=15 model parameters
- 9 centrality bins, 2 energies
- Latin hypercube with m=500 points
- $\mathcal{O}(10^4)$ events per point, for a total of approx. 35,000,000 events
- use Gaussian Process Emulators to interpolate between points

Example:

- Latin-hypercube projection for η/s parameters



Computer Experiment Execution

Edison @ NERSC:

- Cray XC30: 5586 nodes w/ 24 cores each
- 2 hyperthreads per core
- 2.57 Petaflops/s

Duke QCD workflow:

- 1000 nodes per job: running on 48K cores simultaneously
- entire model design with 30M events can be computed in 1 day

NOW COMPUTING

A small sample of massively parallel scientific computing jobs running right now at NERSC.

Calibration

Vector of input parameters: $\mathbf{x}$=[p,k,w,$(\eta/s)_{min}$,$(\eta/s)_{slope}$,$(\zeta/s)_{norm}$,T_{sw},…]

- assume true parameters $\mathbf{x}_\star$ exist ⇒ find probability distribution for $\mathbf{x}_\star$

- X: training data design points
- Y: model output on X

Bayes' Theorem: $P(\mathbf{x}_\star | X,Y,\mathbf{y}_{exp}) \propto P(X,Y,\mathbf{y}_{exp} | \mathbf{x}_\star) P(\mathbf{x}_\star)$

- $P(\mathbf{x}_\star)$ = prior
  ⇒ initial knowledge of $\mathbf{x}_\star$

- $P(\mathbf{x}_\star | X,Y,\mathbf{y}_{exp})$ = posterior
  ⇒ probability of $\mathbf{x}_\star$ given observations $(X,Y,\mathbf{y}_{exp})$

- $P(X,Y,\mathbf{y}_{exp} | \mathbf{x}_\star)$ = likelihood
  ⇒ probability of observing $(X,Y,\mathbf{y}_{exp})$ given proposed $\mathbf{x}_\star$

Markov-Chain Monte-Carlo:

- random walk through parameter space weighted by posterior
- large number of samples
  ⇒ chain equilibrates to posterior distribution
- flat prior within design range, zero outside
- posterior ~ likelihood within design range, zero outside

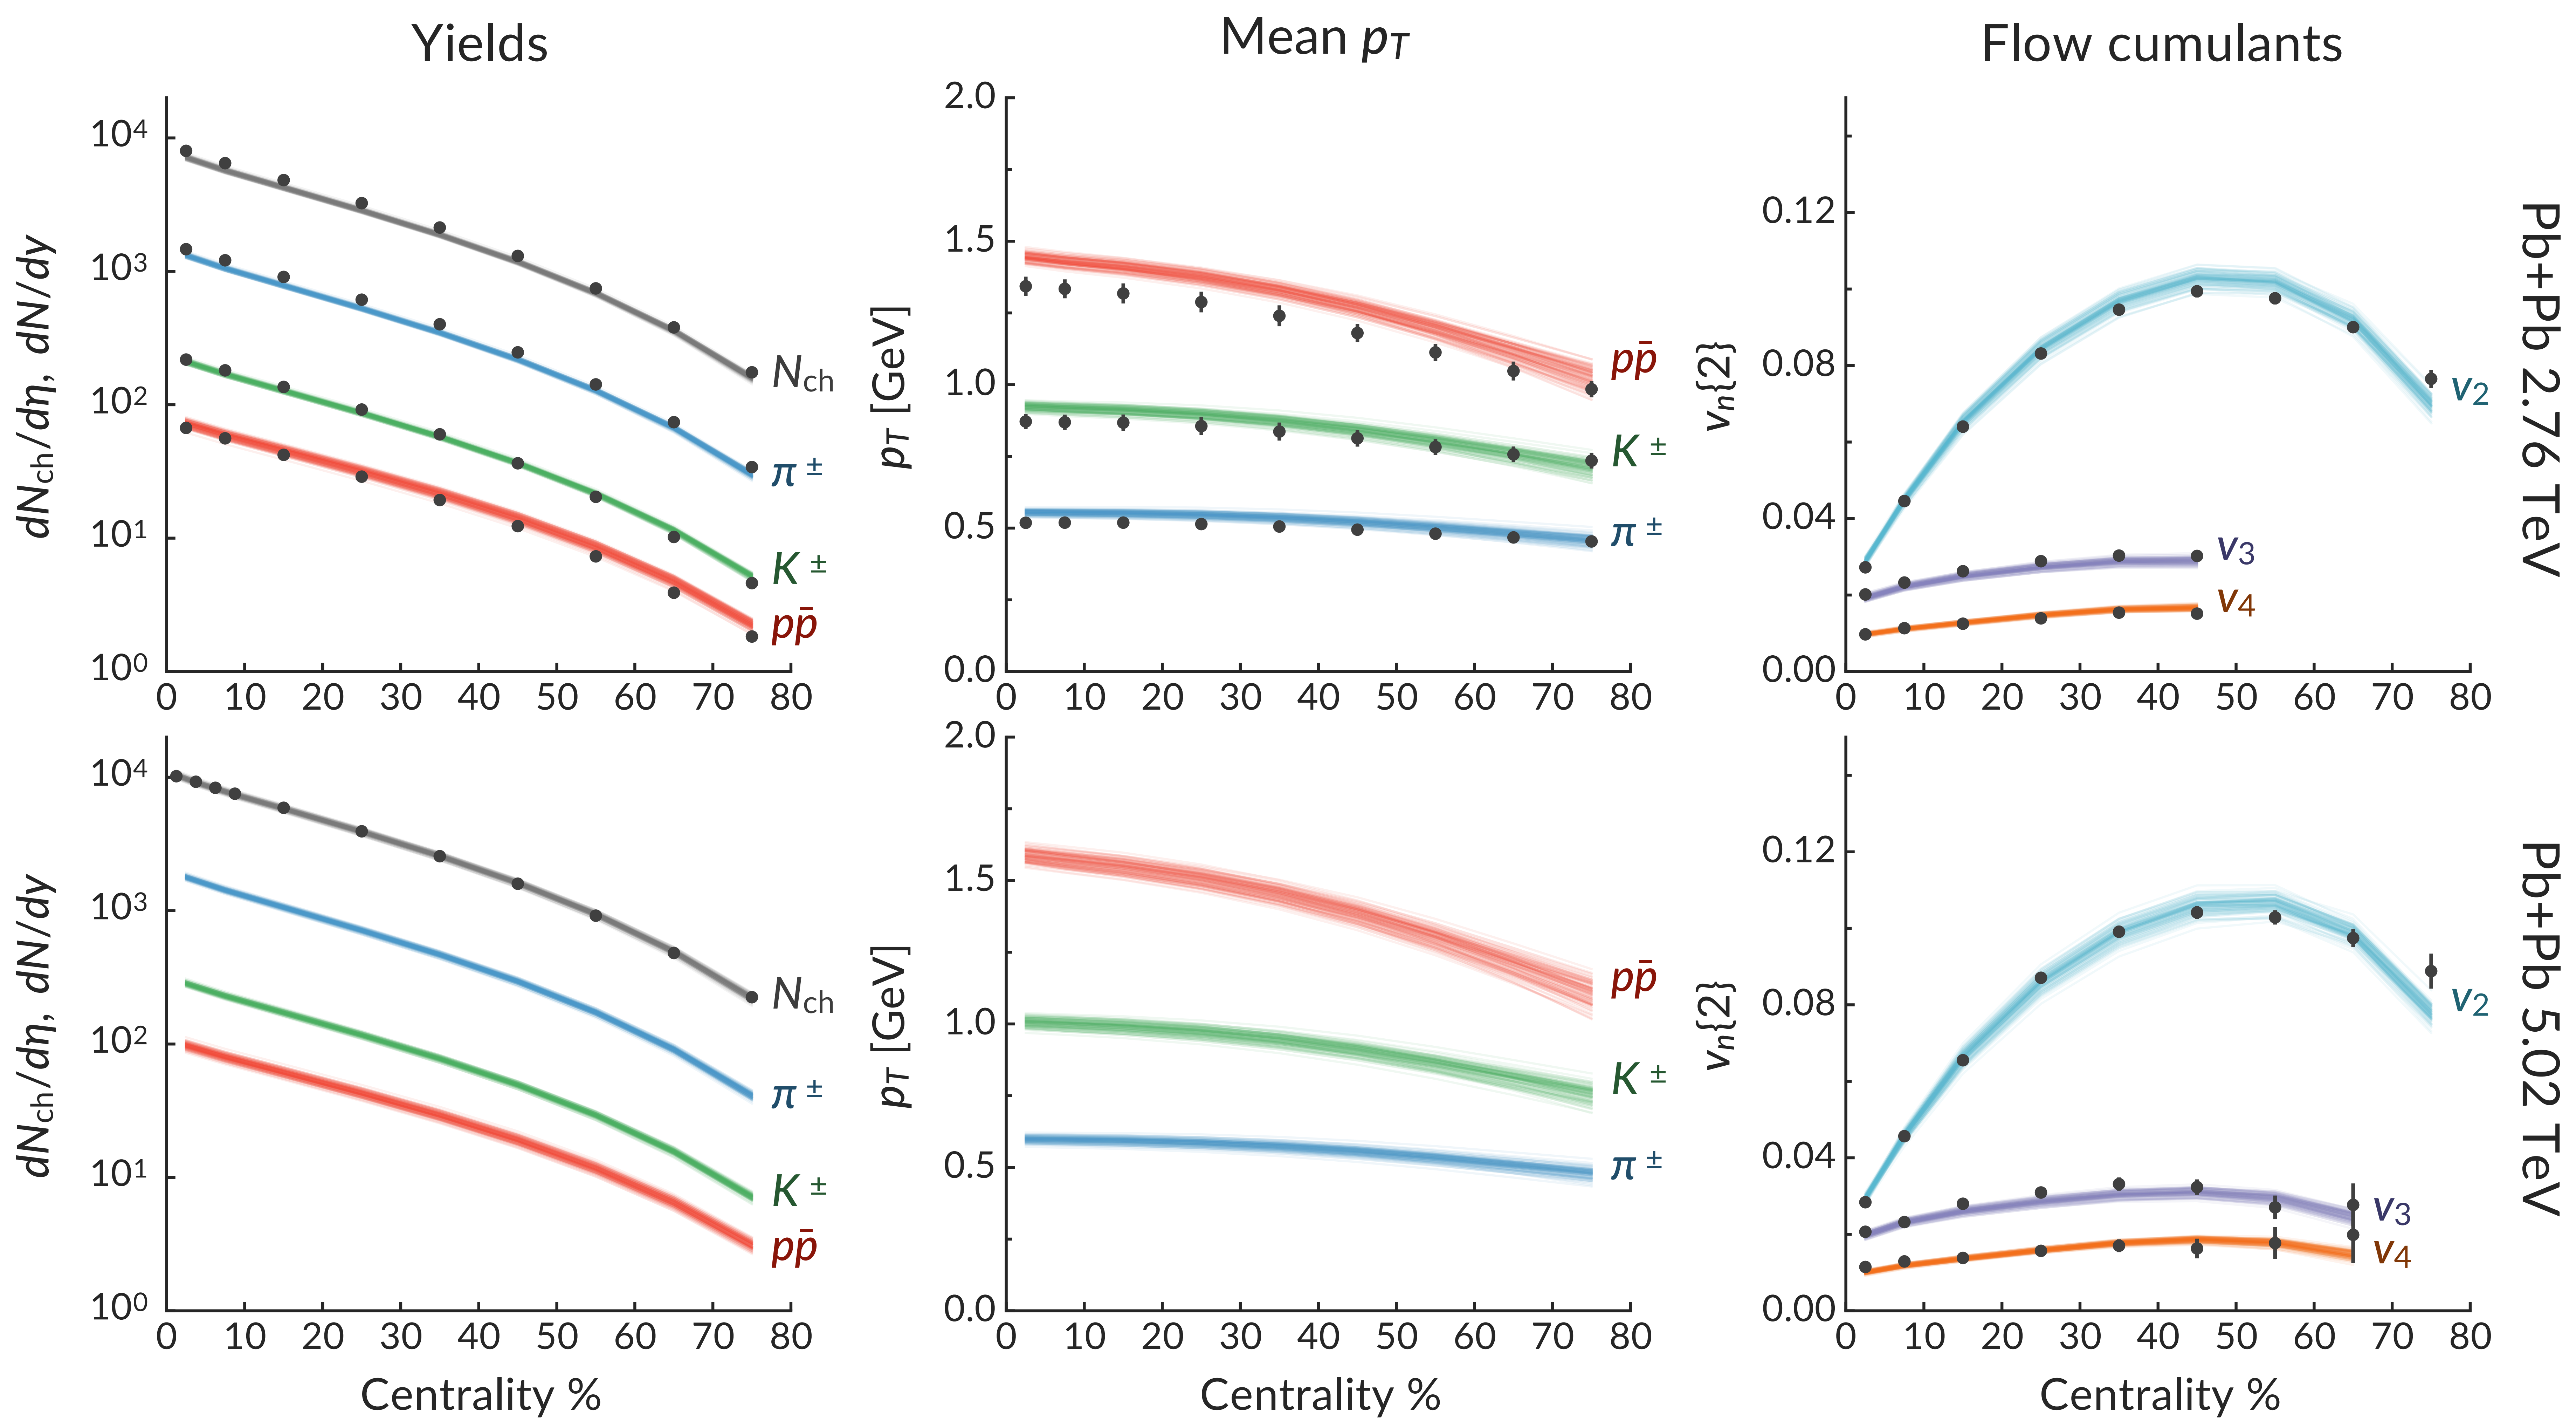
Likelihood and Uncertainty Quantification:

Likelihood $\propto \exp[-1/2\,(\mathbf{y}-\mathbf{y}_{exp})^T \boldsymbol{\Sigma}^{-1} (\mathbf{y}-\mathbf{y}_{exp})]$

- covariance matrix $\boldsymbol{\Sigma} = \boldsymbol{\Sigma}_{experiment} + \boldsymbol{\Sigma}_{model}$
- $\boldsymbol{\Sigma}_{experiment}$=stat(diagonal) + sys(non-diagonal)
- $\boldsymbol{\Sigma}_{model}$ conservatively estimated as 5%

Prior vs. Posterior

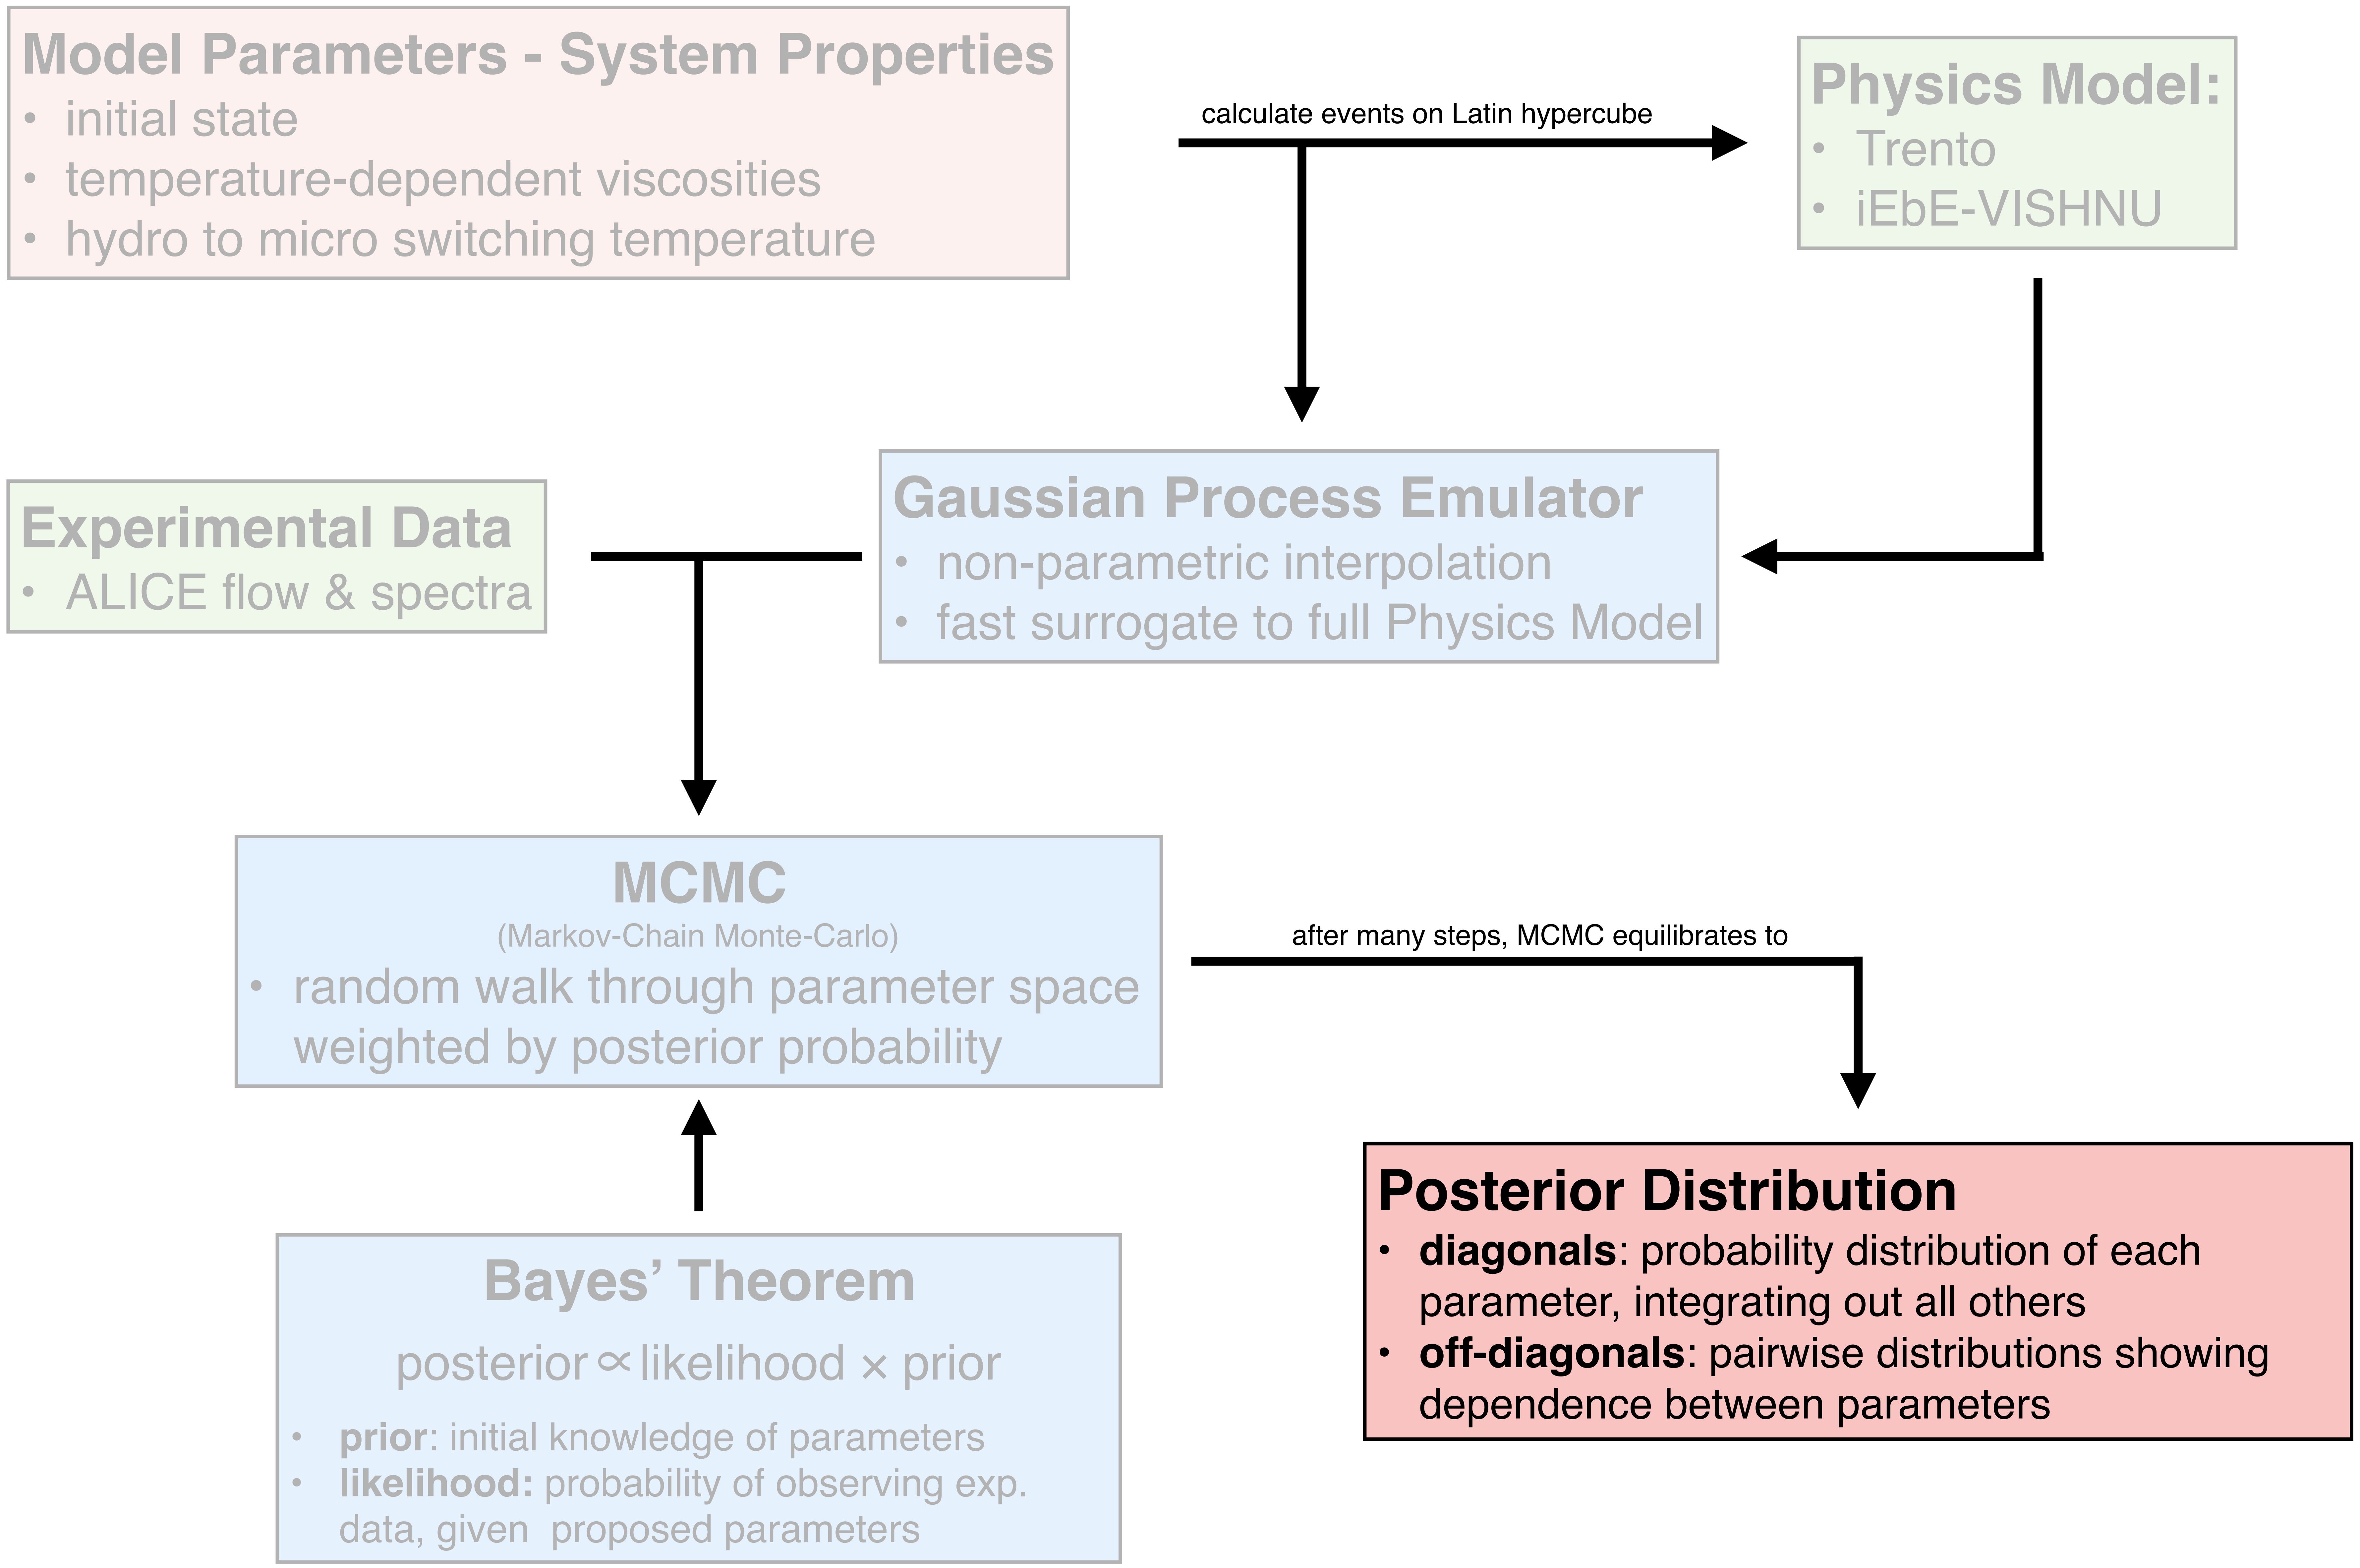
Posterior: emulator predictions for highest likelihood parameter values



Analysis Results

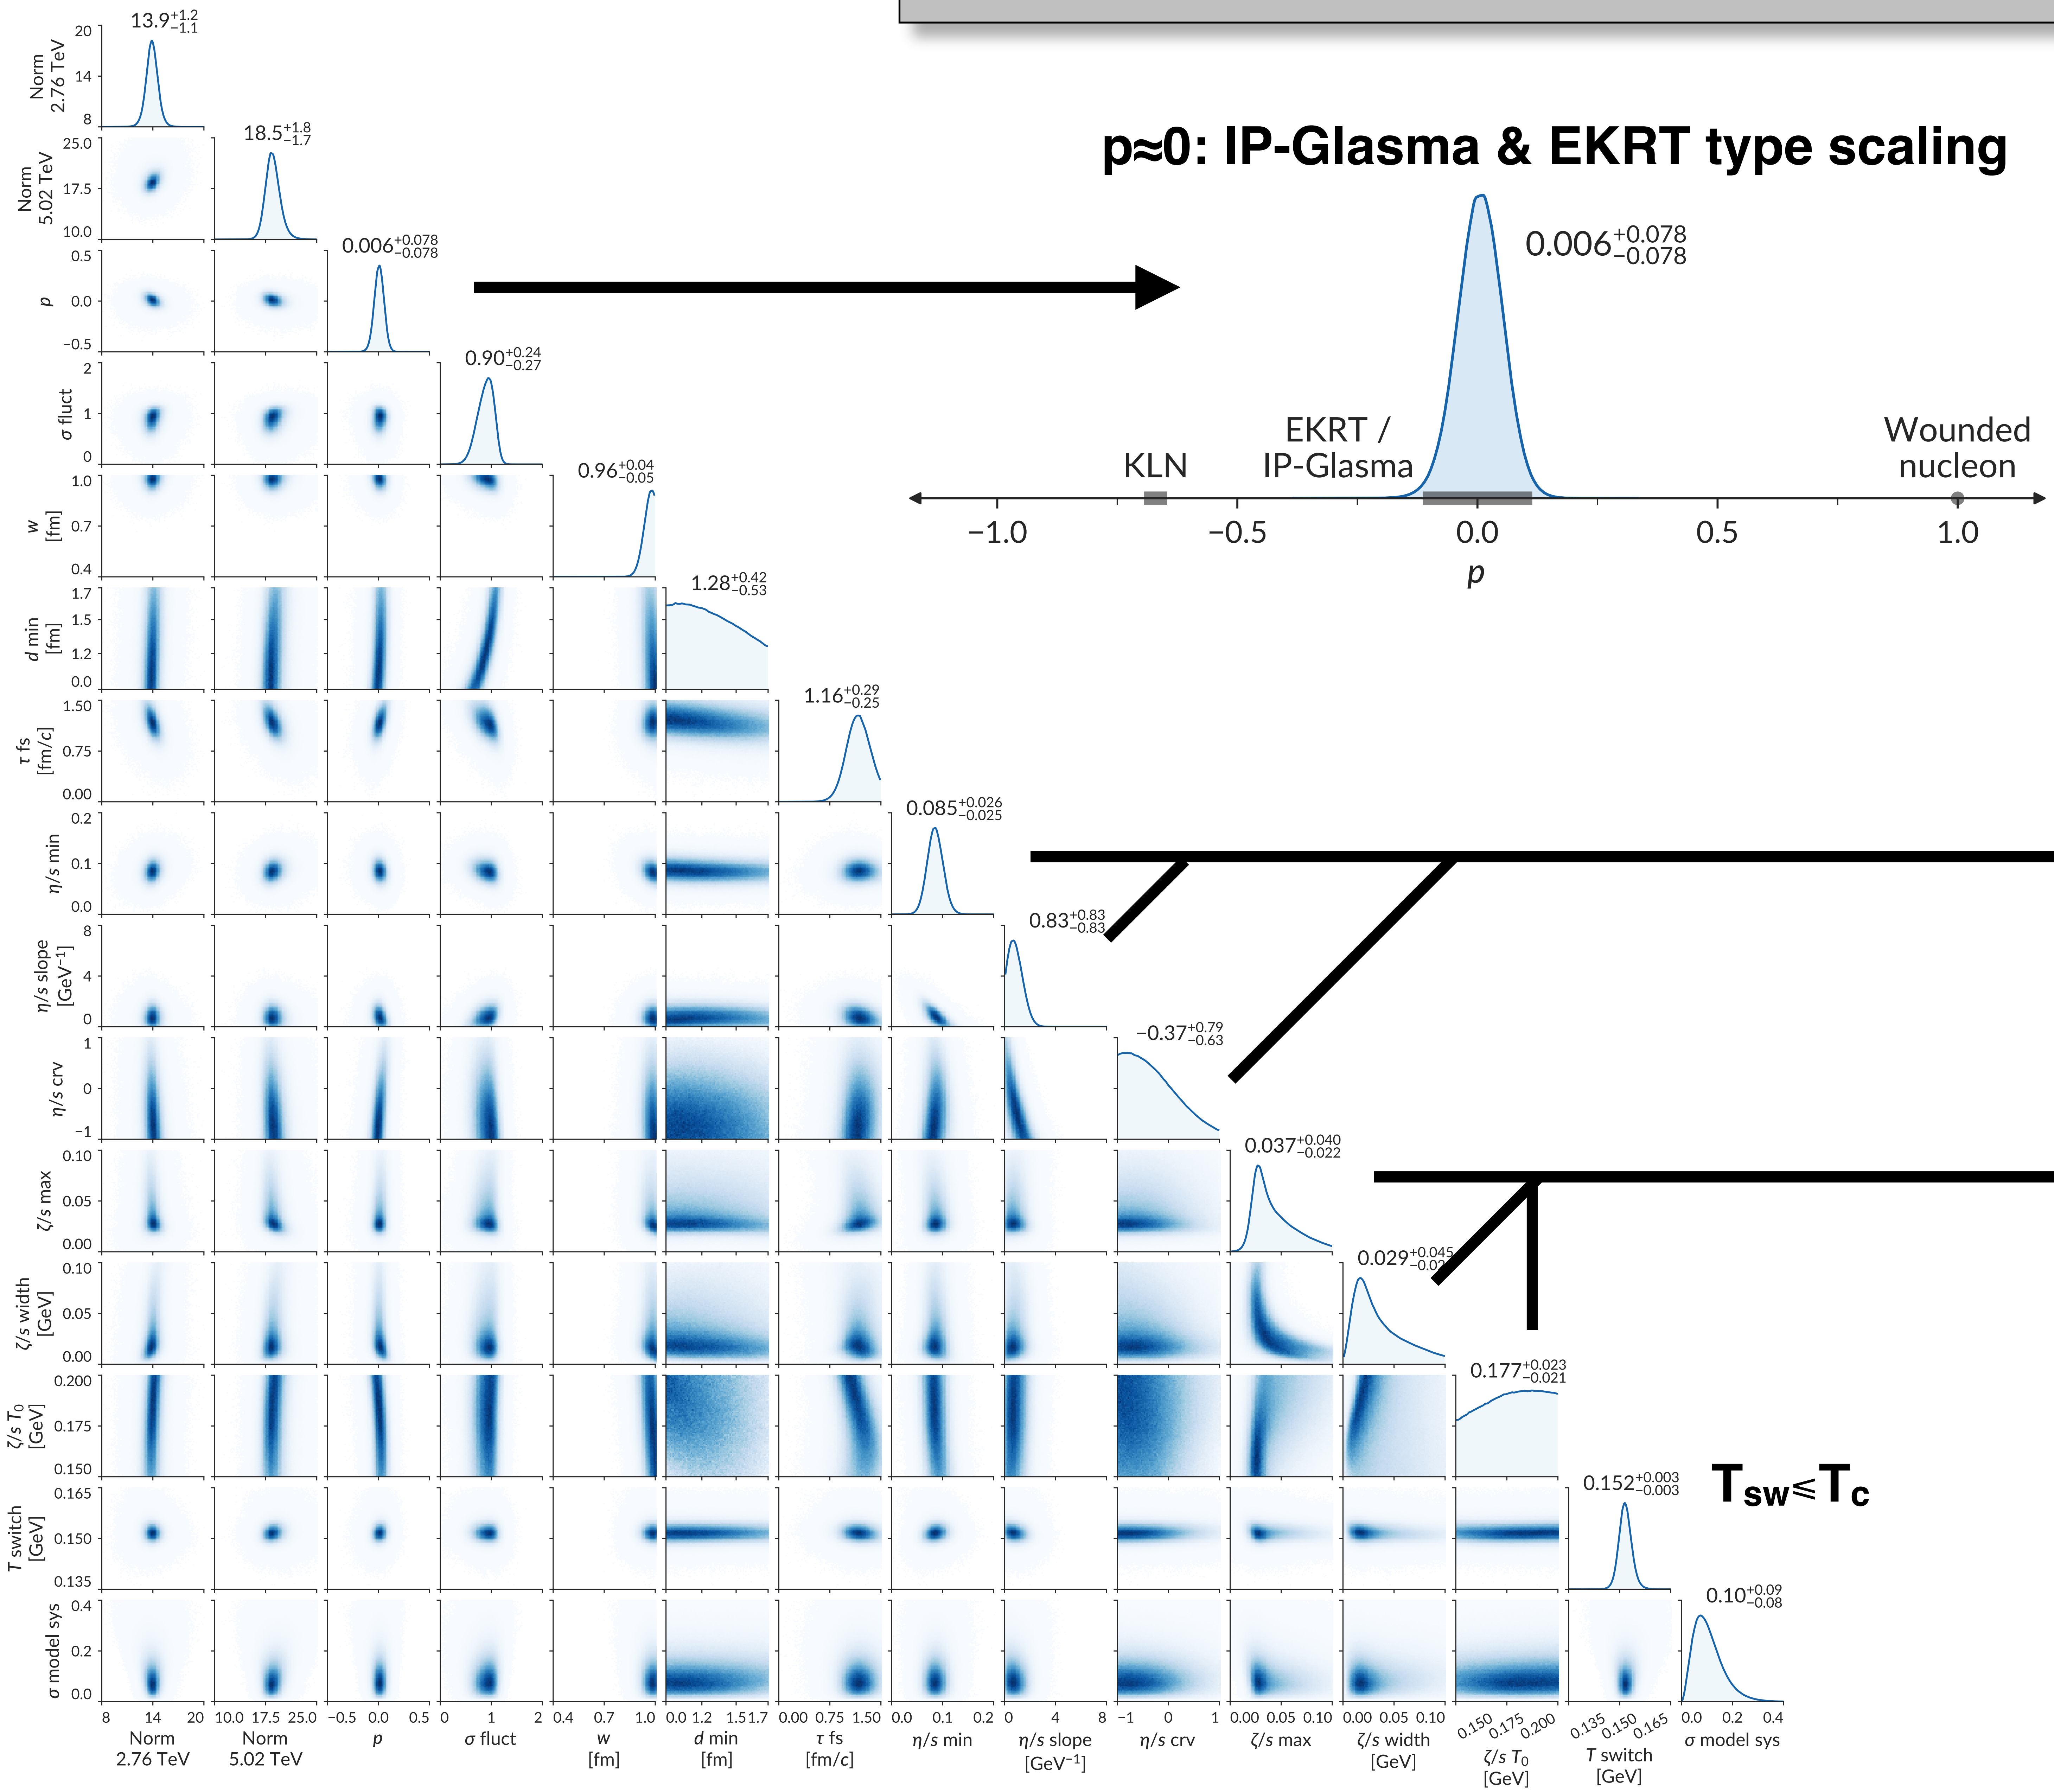
Methodology: Jonah E. Bernhard, J. Scott Moreland, Steffen A. Bass, Jia Liu, Ulrich Heinz: PRC94 (2016) 024907, arXiv:1605.03954
Results: Jonah E. Bernhard, PhD thesis arXiv:1804.06469

Methodology



Calibrated Posterior Distribution

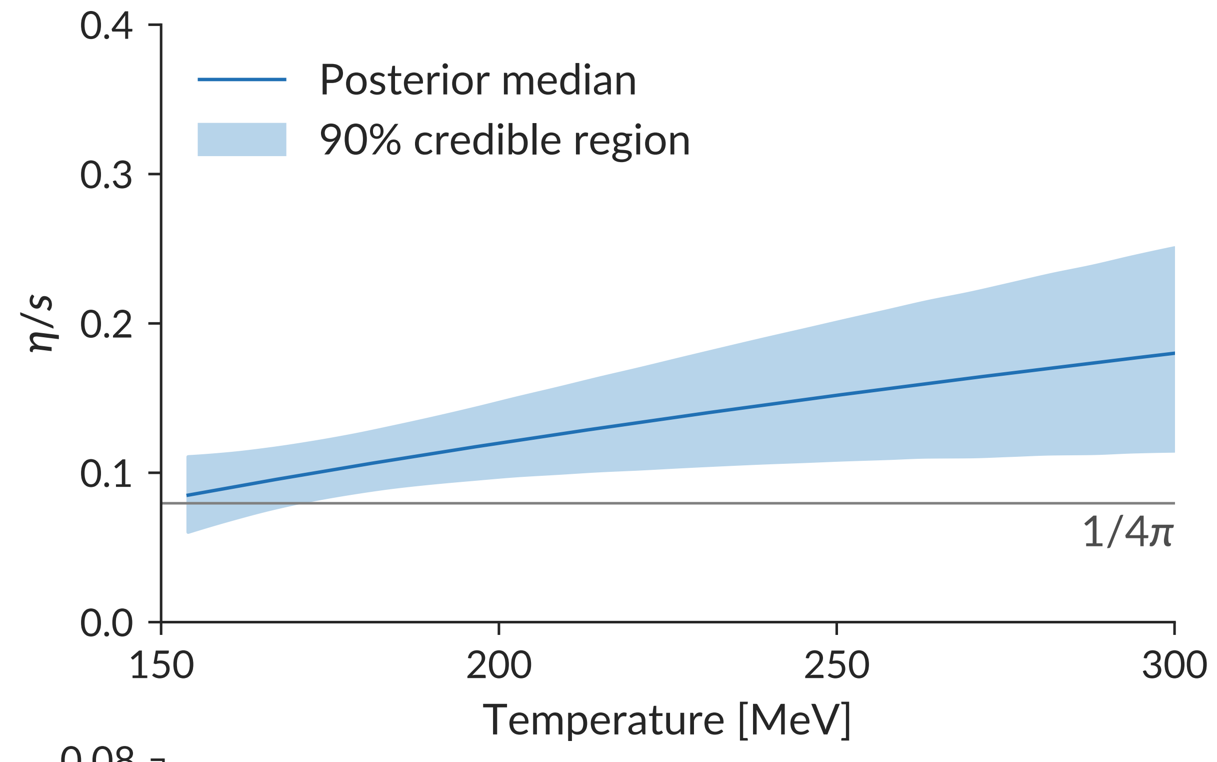
p≈0: IP-Glasma & EKRT type scaling

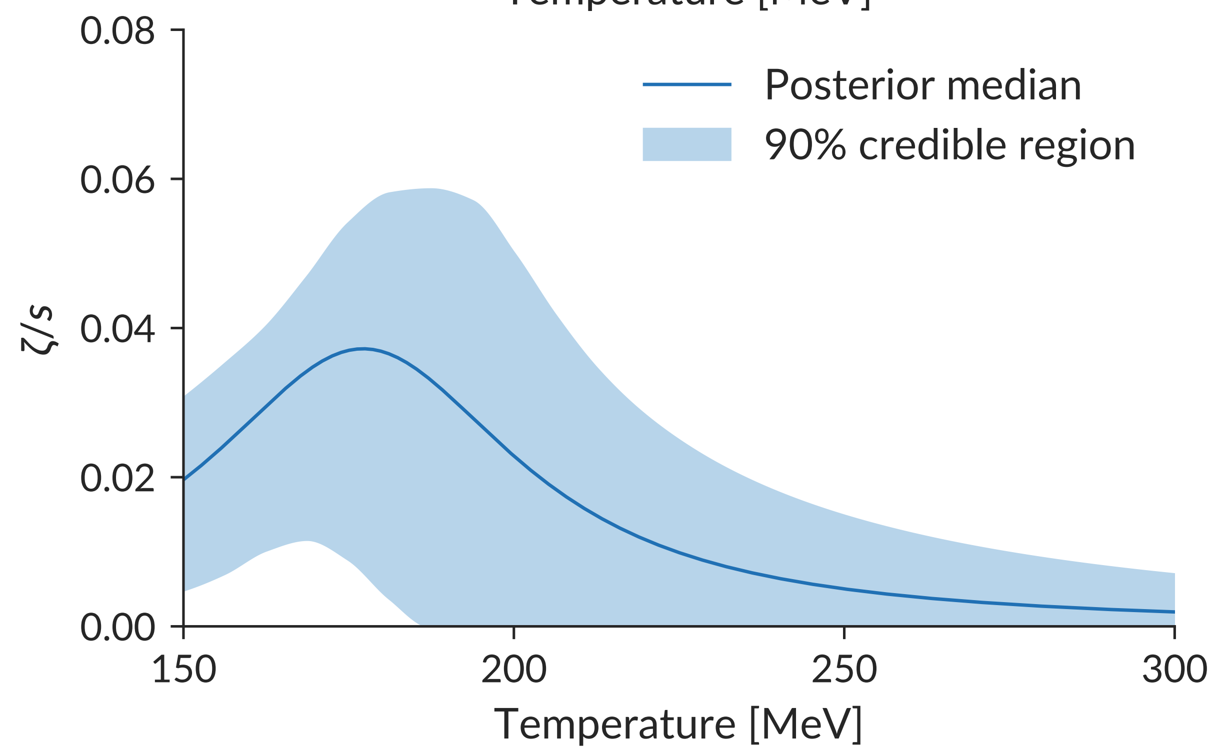


$T_{sw} \lesssim T_c$

- **diagonals**: probability distribution of each parameter, integrating out all others
- **off-diagonals**: pairwise distributions showing dependence between parameters

temperature-dependent viscosities:



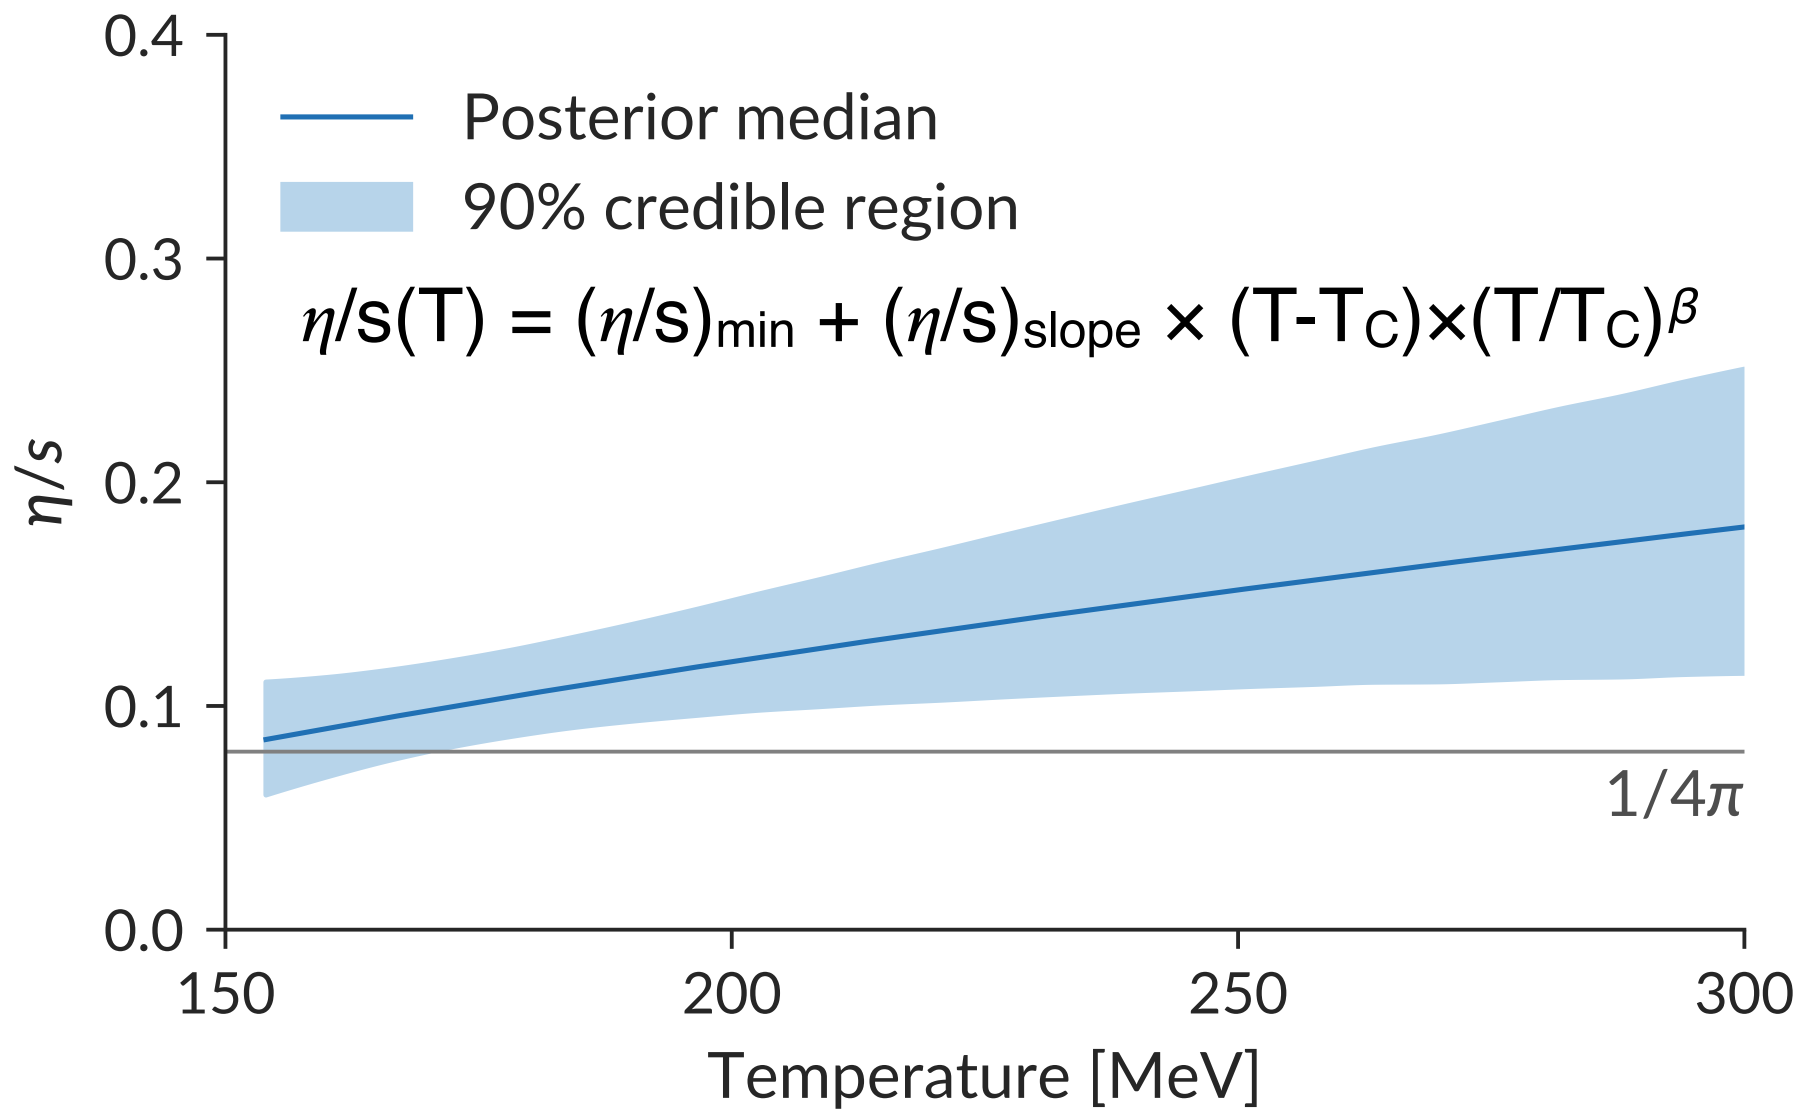


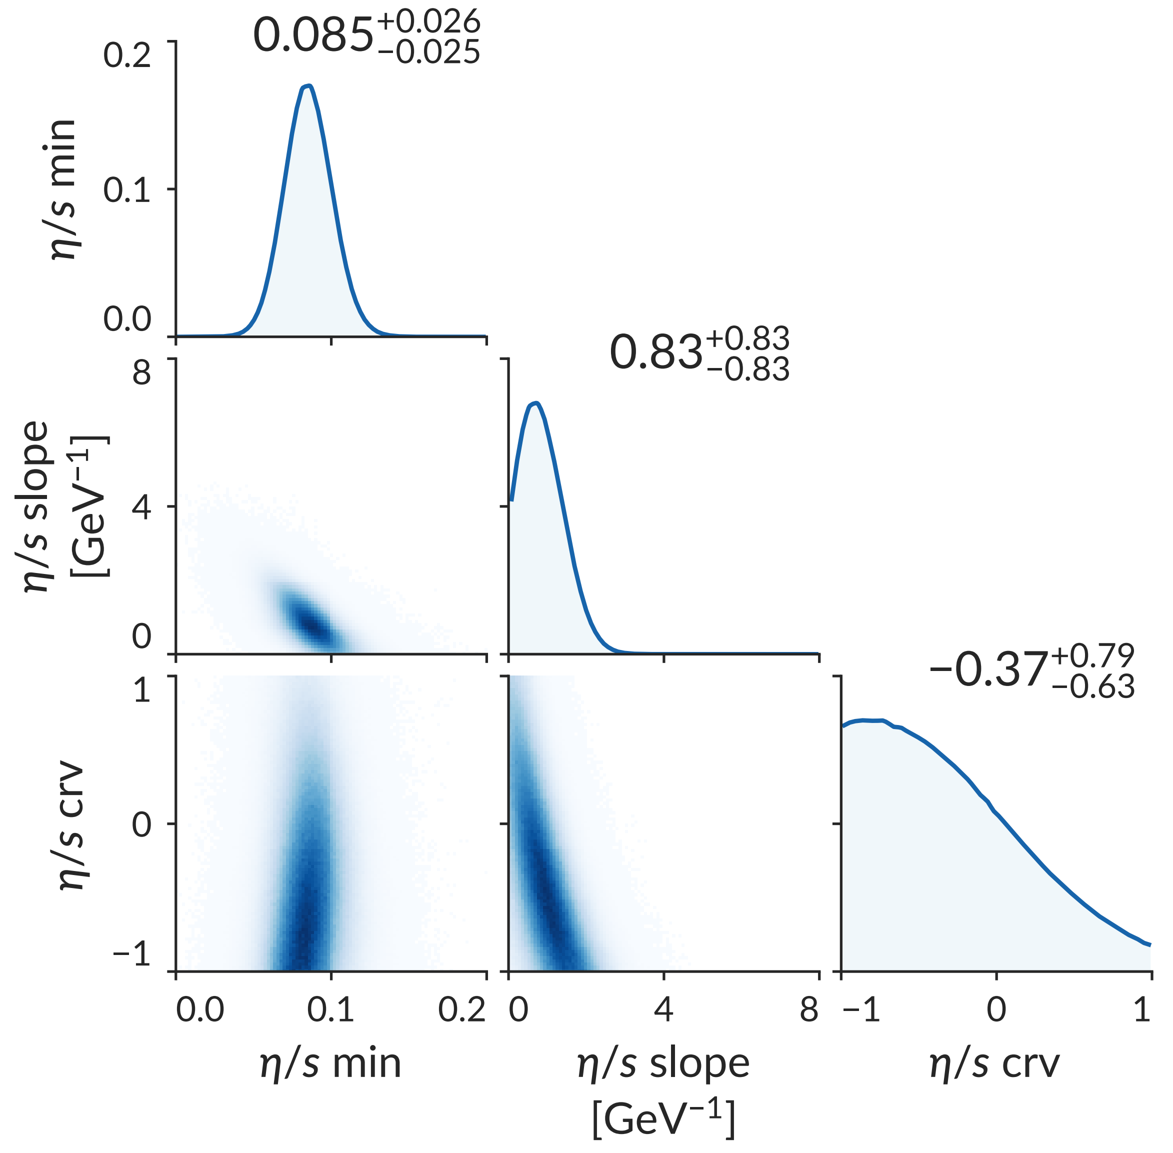
Temperature Dependence of Shear & Bulk Viscosities

temperature dependent shear viscosity:

- analysis favors small value and shallow rise
- results do not fully constrain temperature dependence:
  - inverse correlation between $(\eta/s)_{slope}$ slope and intercept $(\eta/s)_{min}$
  - insufficient data to obtain sharply peaked likelihood distributions for $(\eta/s)_{slope}$ and curvature β independently
- current analysis most sensitive to T< 0.23 GeV

▸ **RHIC data may disambiguate further**



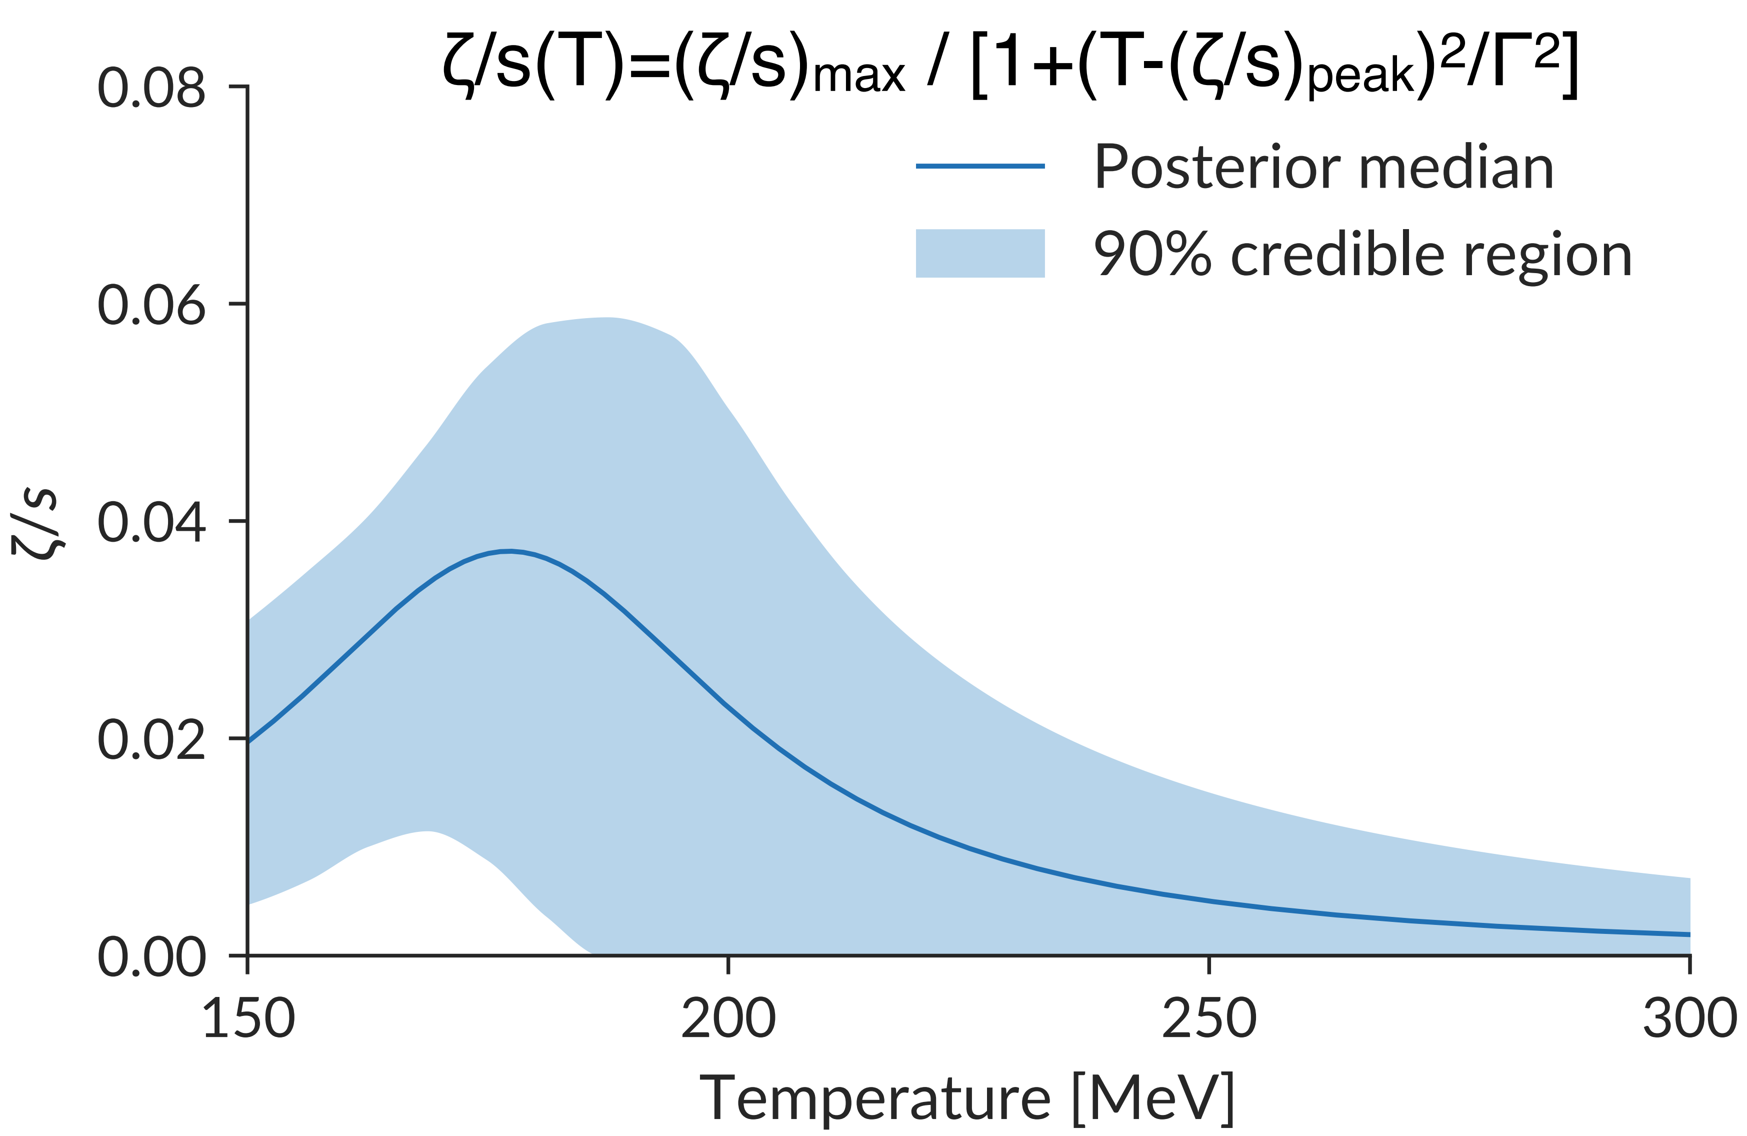


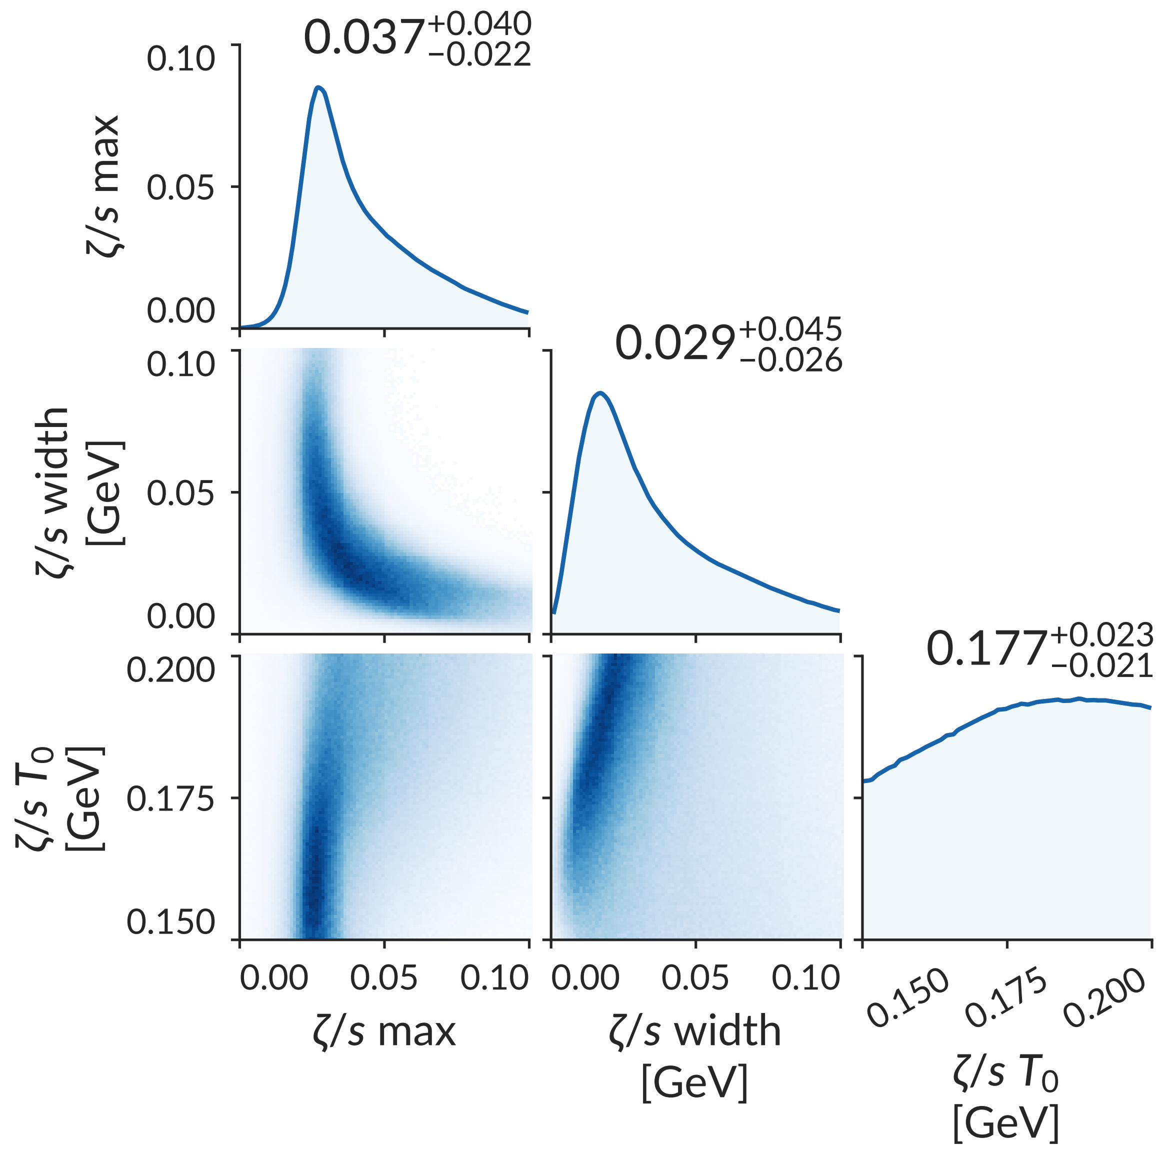
temperature dependent bulk viscosity:

- setup of analysis allows for vanishing value of bulk viscosity
- significant non-zero value near T_C favored, confirming the presence / need for bulk viscosity

caveat of current analysis:

- bulk-viscous corrections are implemented using relaxation-time approximation & regulated to prevent negative particle densities

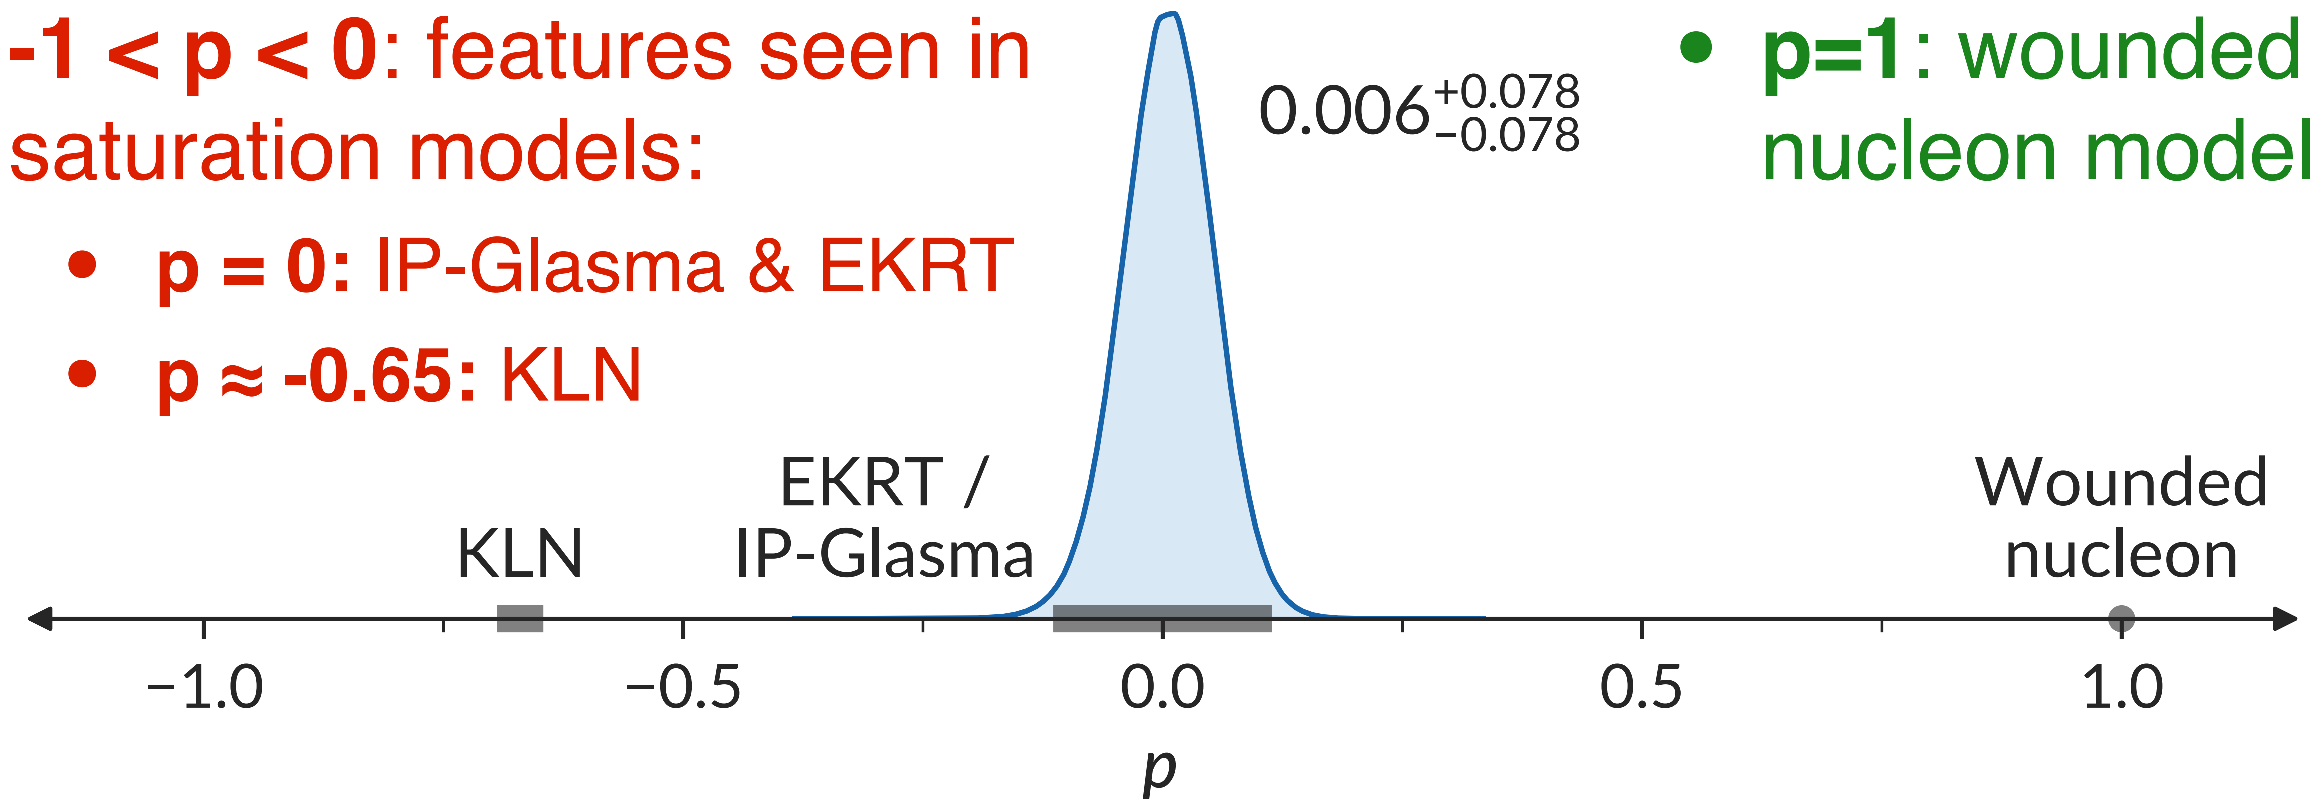




Constraining the Initial State

p quantifies the attenuation of entropy production in the off-diagonal regions of $dS/dy \propto T_R(p;T_A,T_B)$:

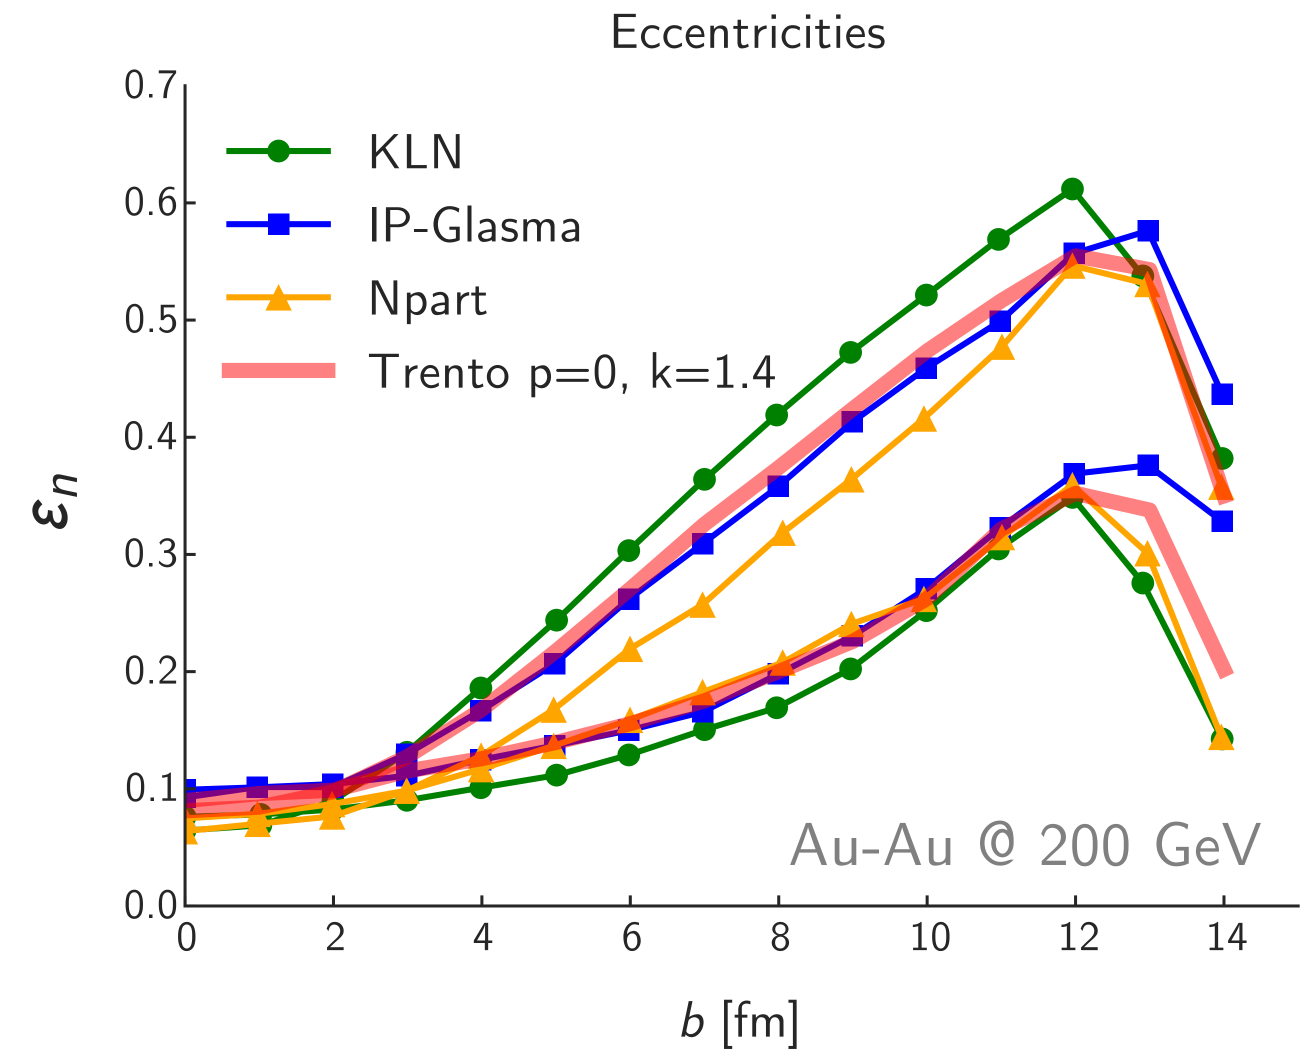
- **-1 < p < 0**: features seen in saturation models:
  - **p = 0:** IP-Glasma & EKRT
  - **p ≈ -0.65:** KLN
- **p=1**: wounded nucleon model

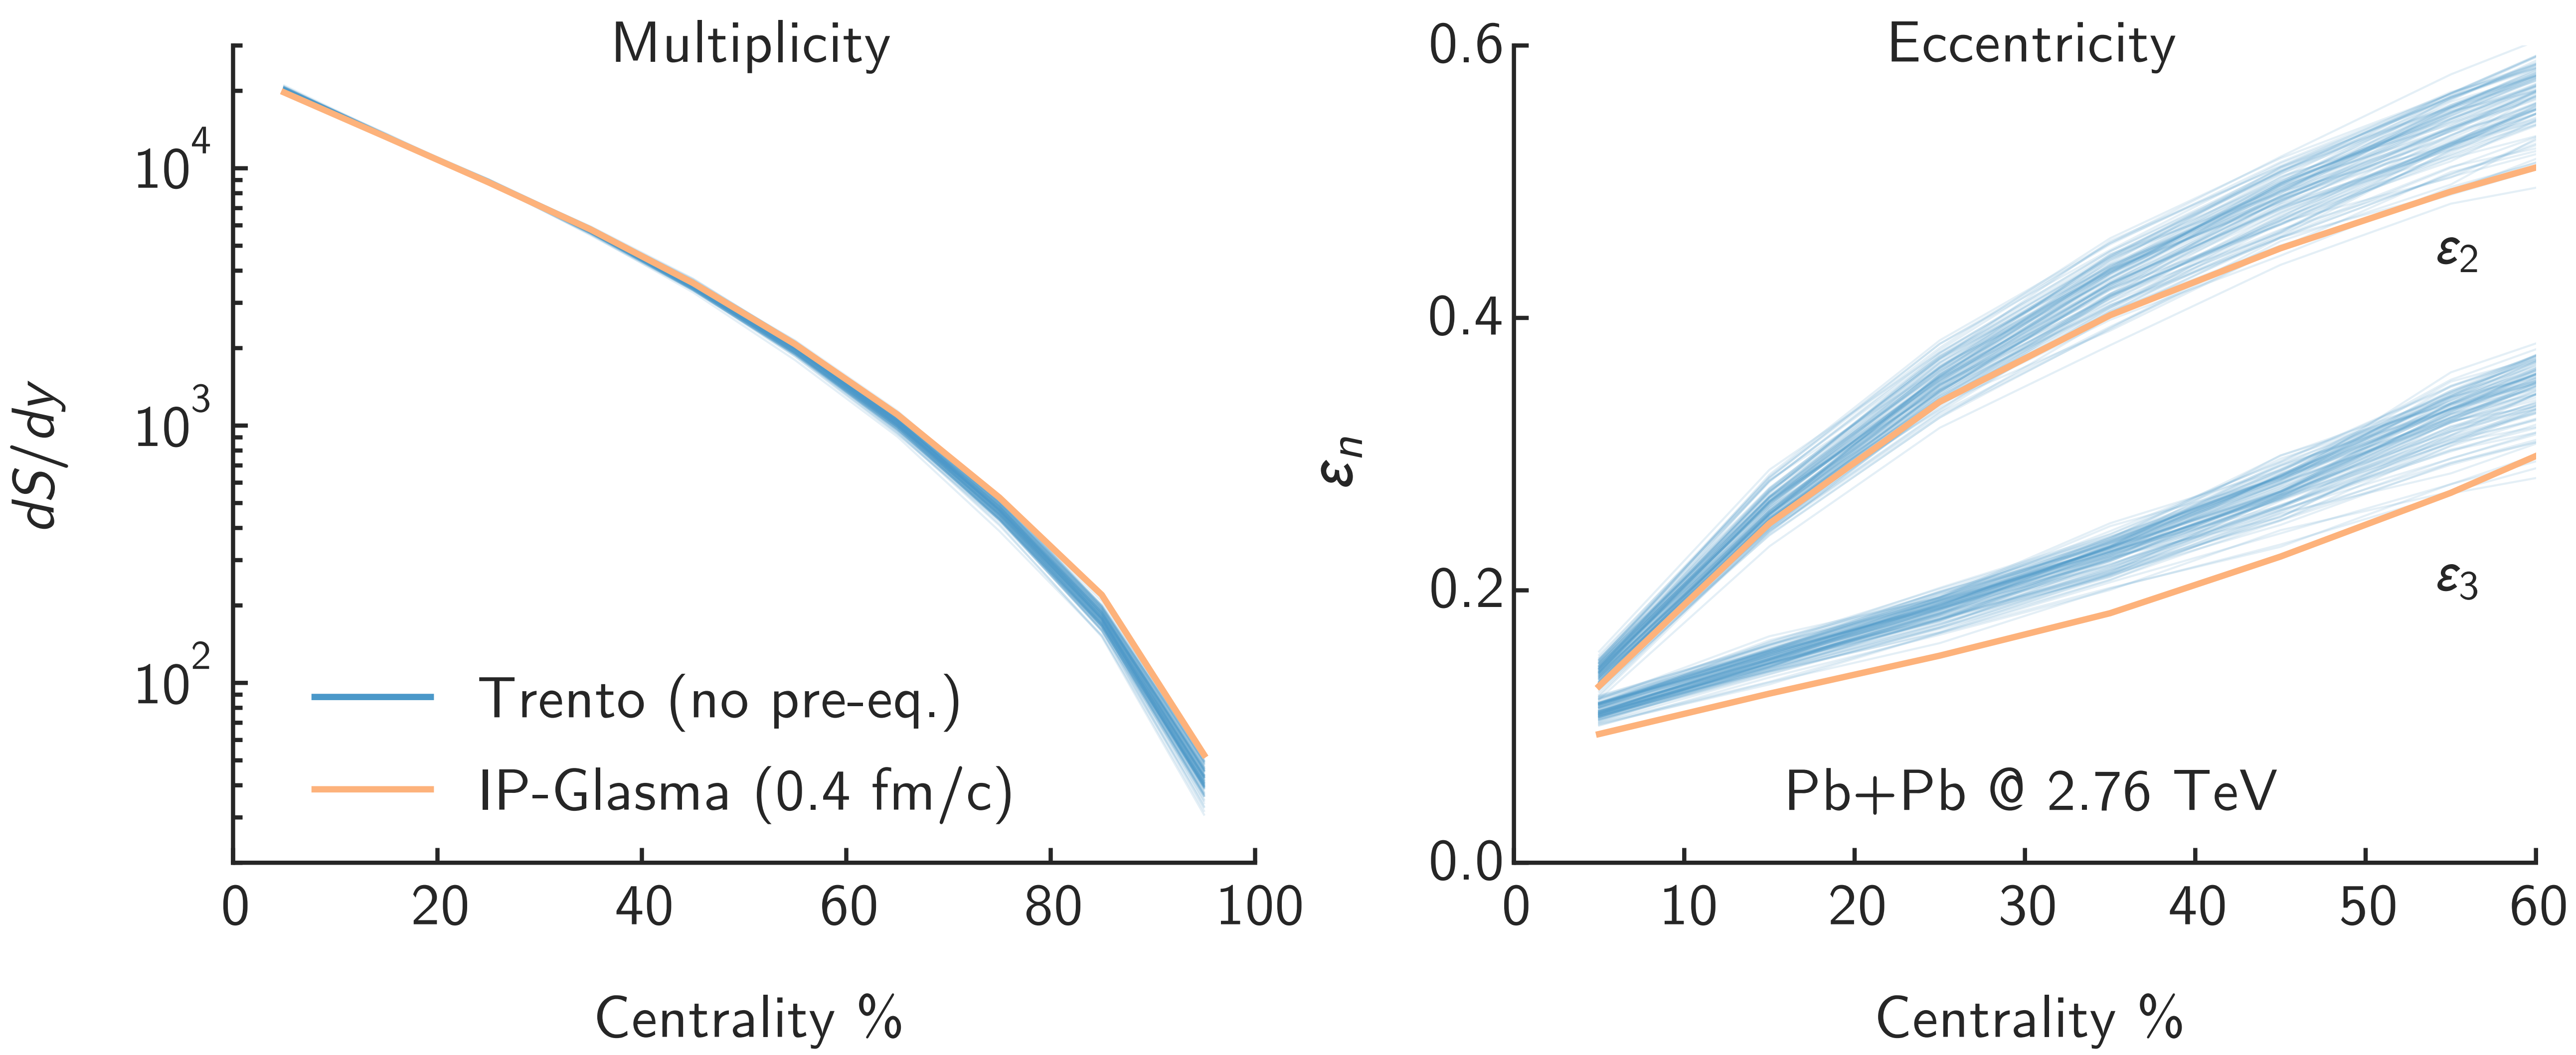


- **analysis strongly favors eccentricity scaling and entropy deposition seen in the EKRT & IP-Glasma models**
- **wounded nucleon and KLN models disfavored**
- **no conclusion yet on 2 component WN+BC model**
- **still need to corroborate scale of fluctuations being probed**

Trento vs. IP-Glasma:

note: no pre-equilibrium flow in the current Trento analysis, may account for larger ε_n

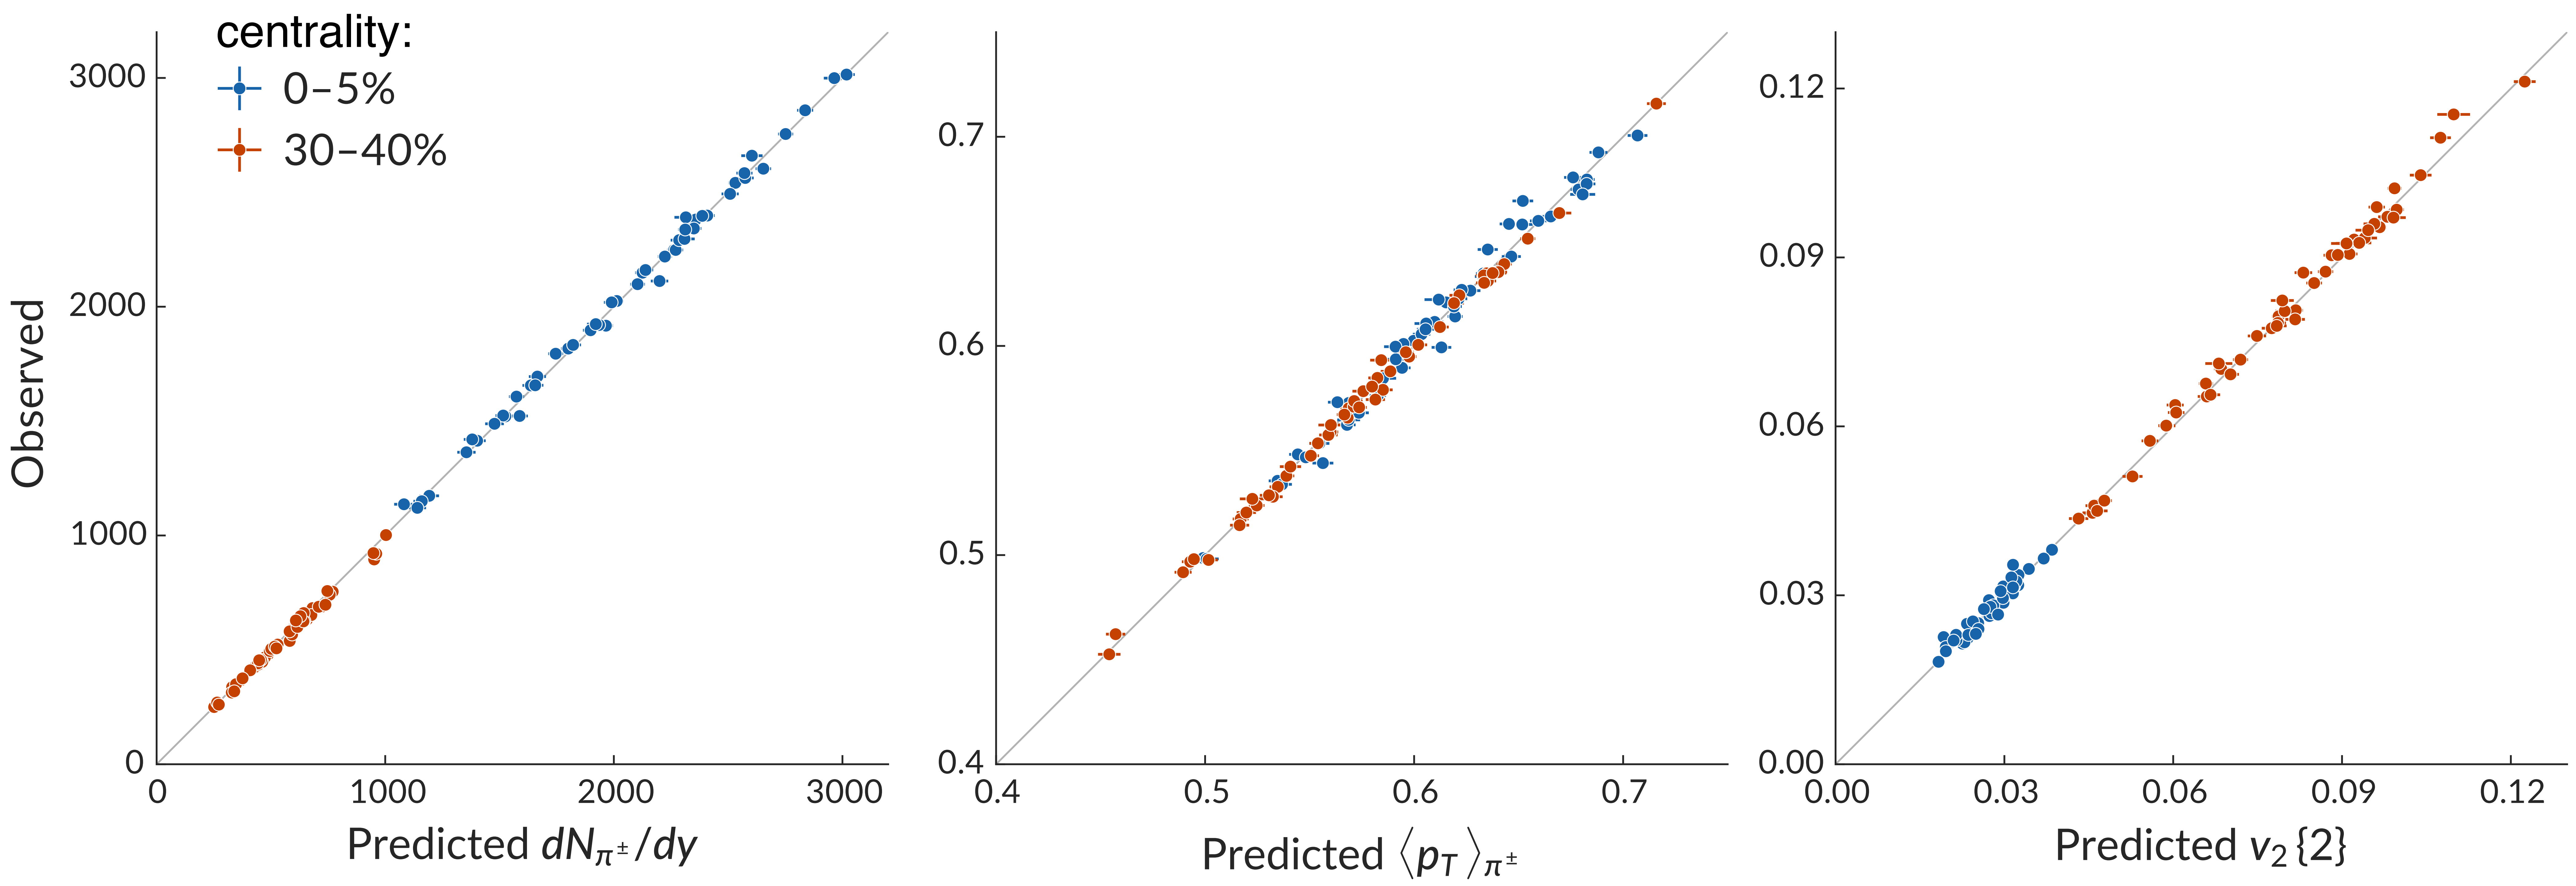




Precision Science
or
“Smoke & Mirrors”?

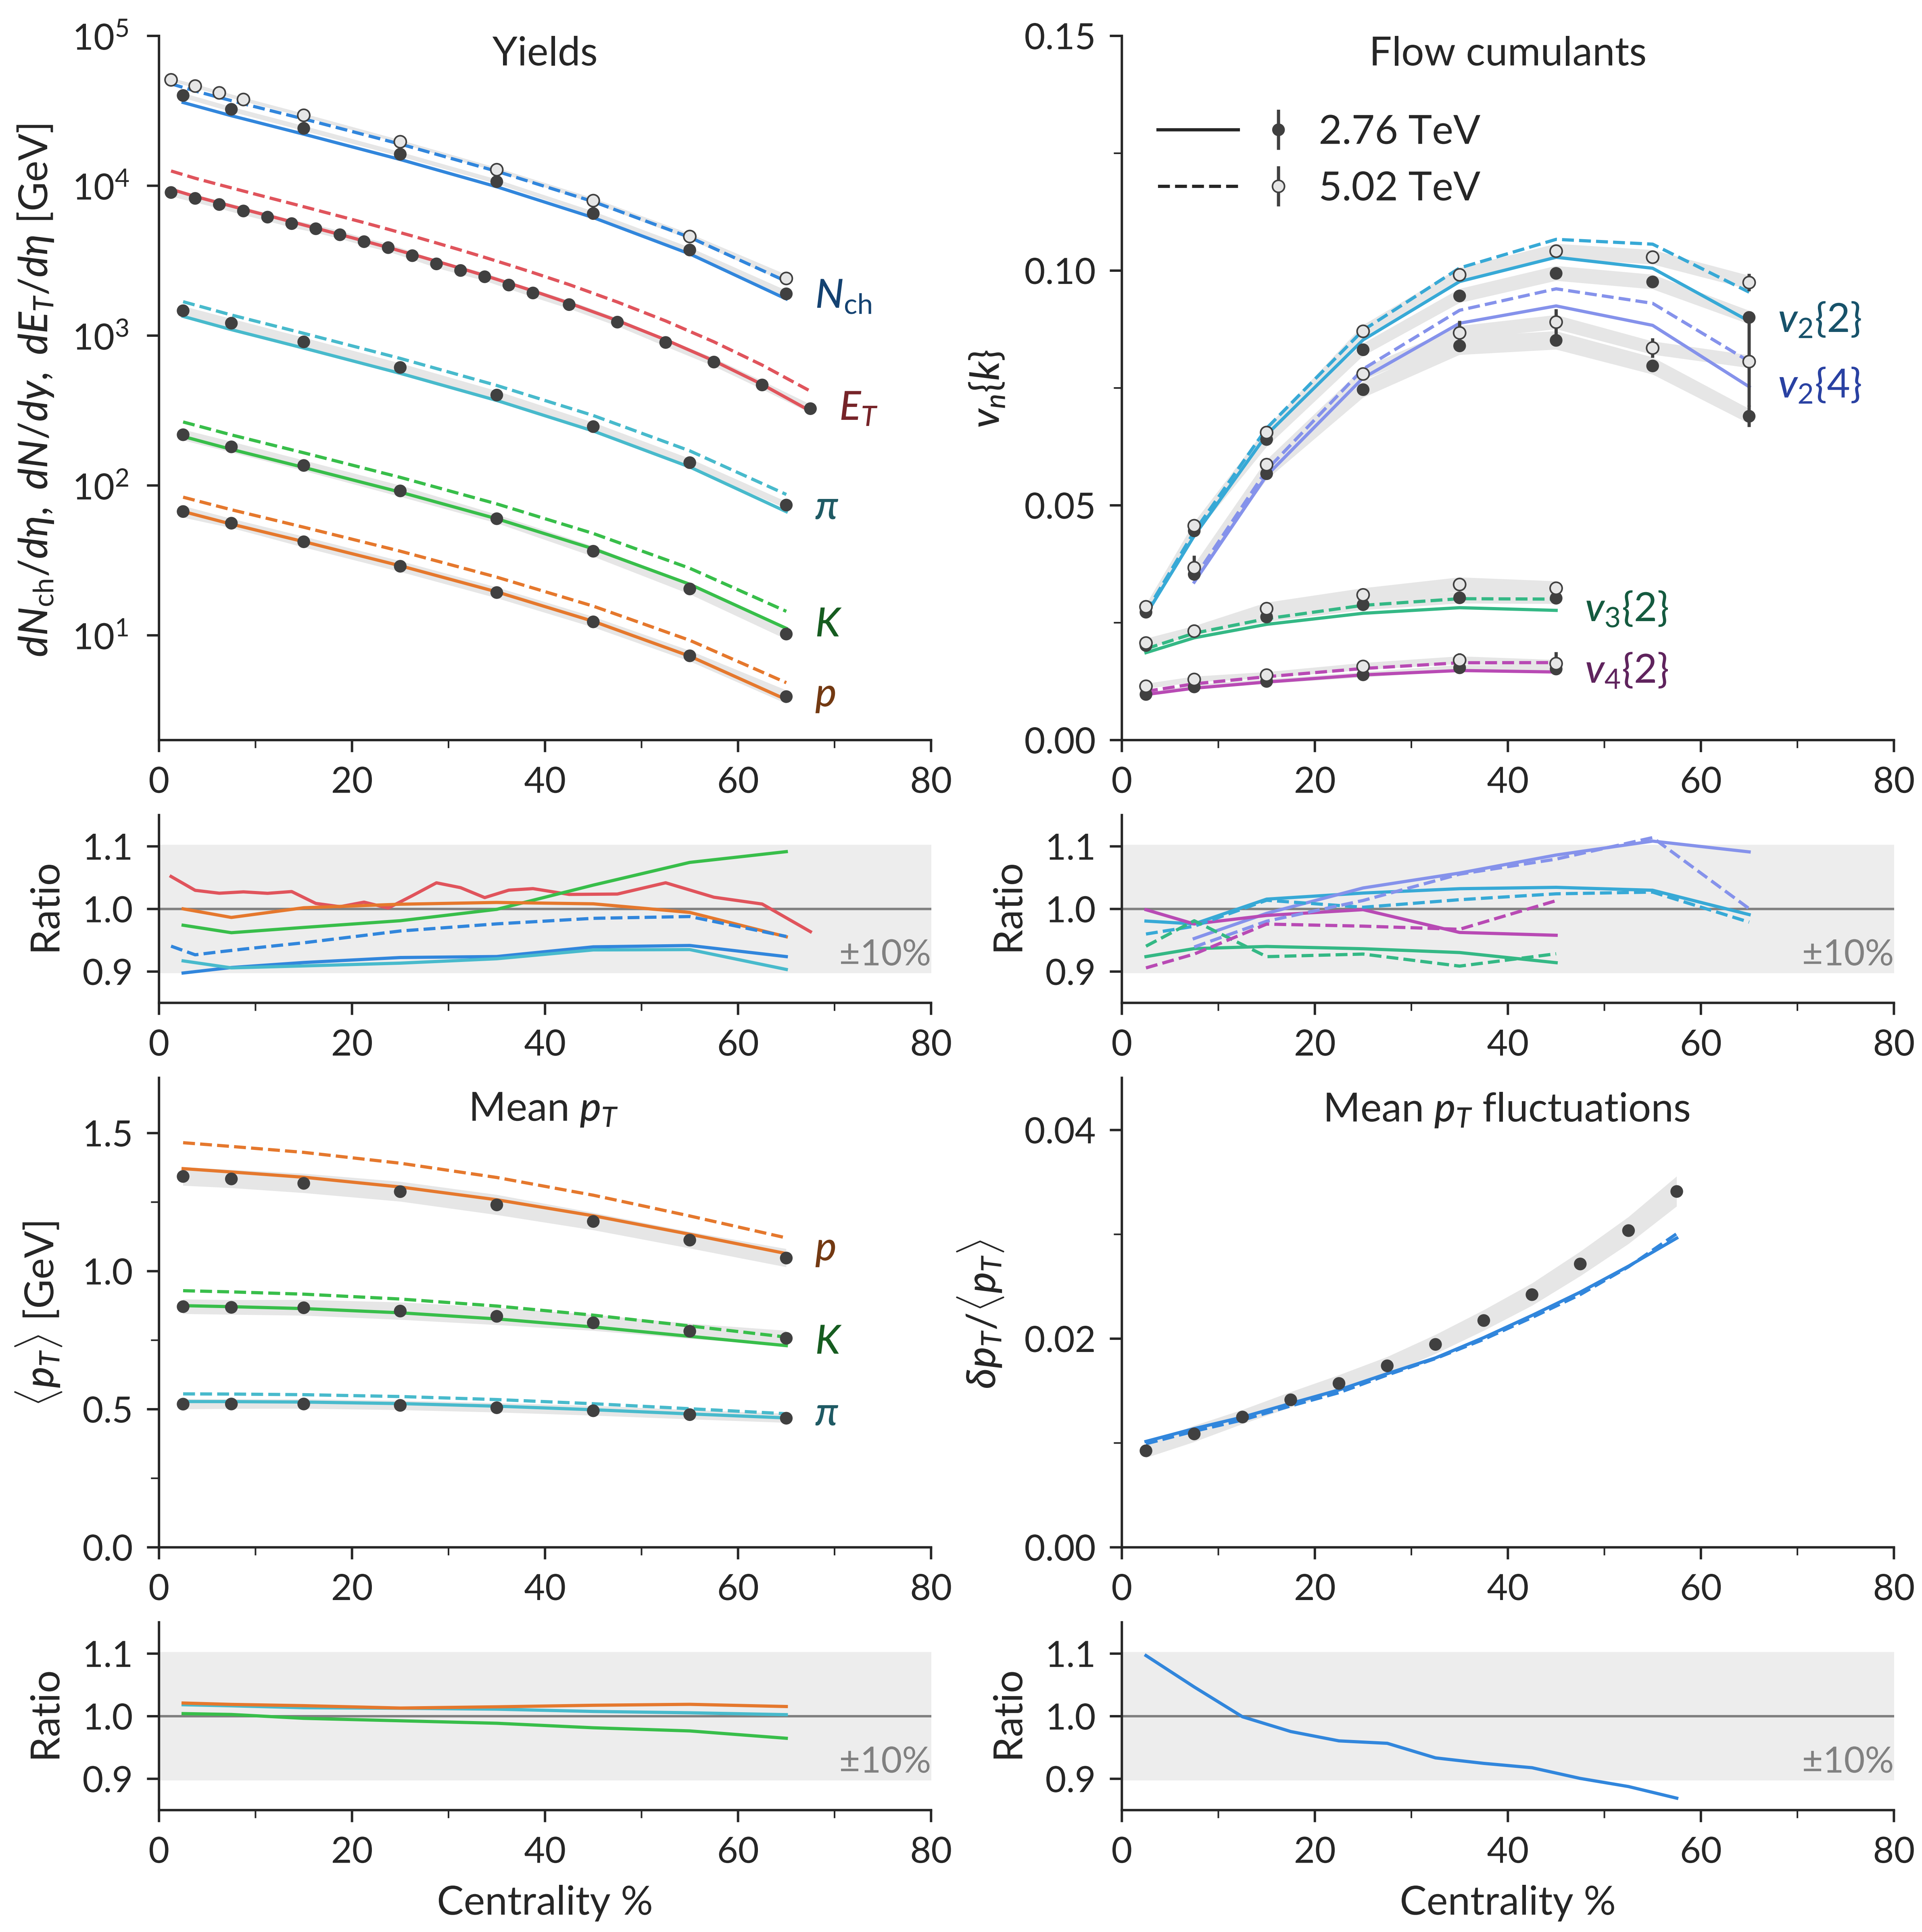
Validation

- generate a separate Latin hypercube validation design with 50 points
- evaluate the full physics model at each validation point
- compare physics model output to that of the previously conditioned GP emulators:



- note that since GPEs are stochastic functions, only ~68% of predictions need to fall within 1 standard deviation

Verification: Explicit Model Calculation



- explicit physics model calculations (no emulator) with parameter values set to the maximum of the posterior probability distributions yield excellent agreement with data!

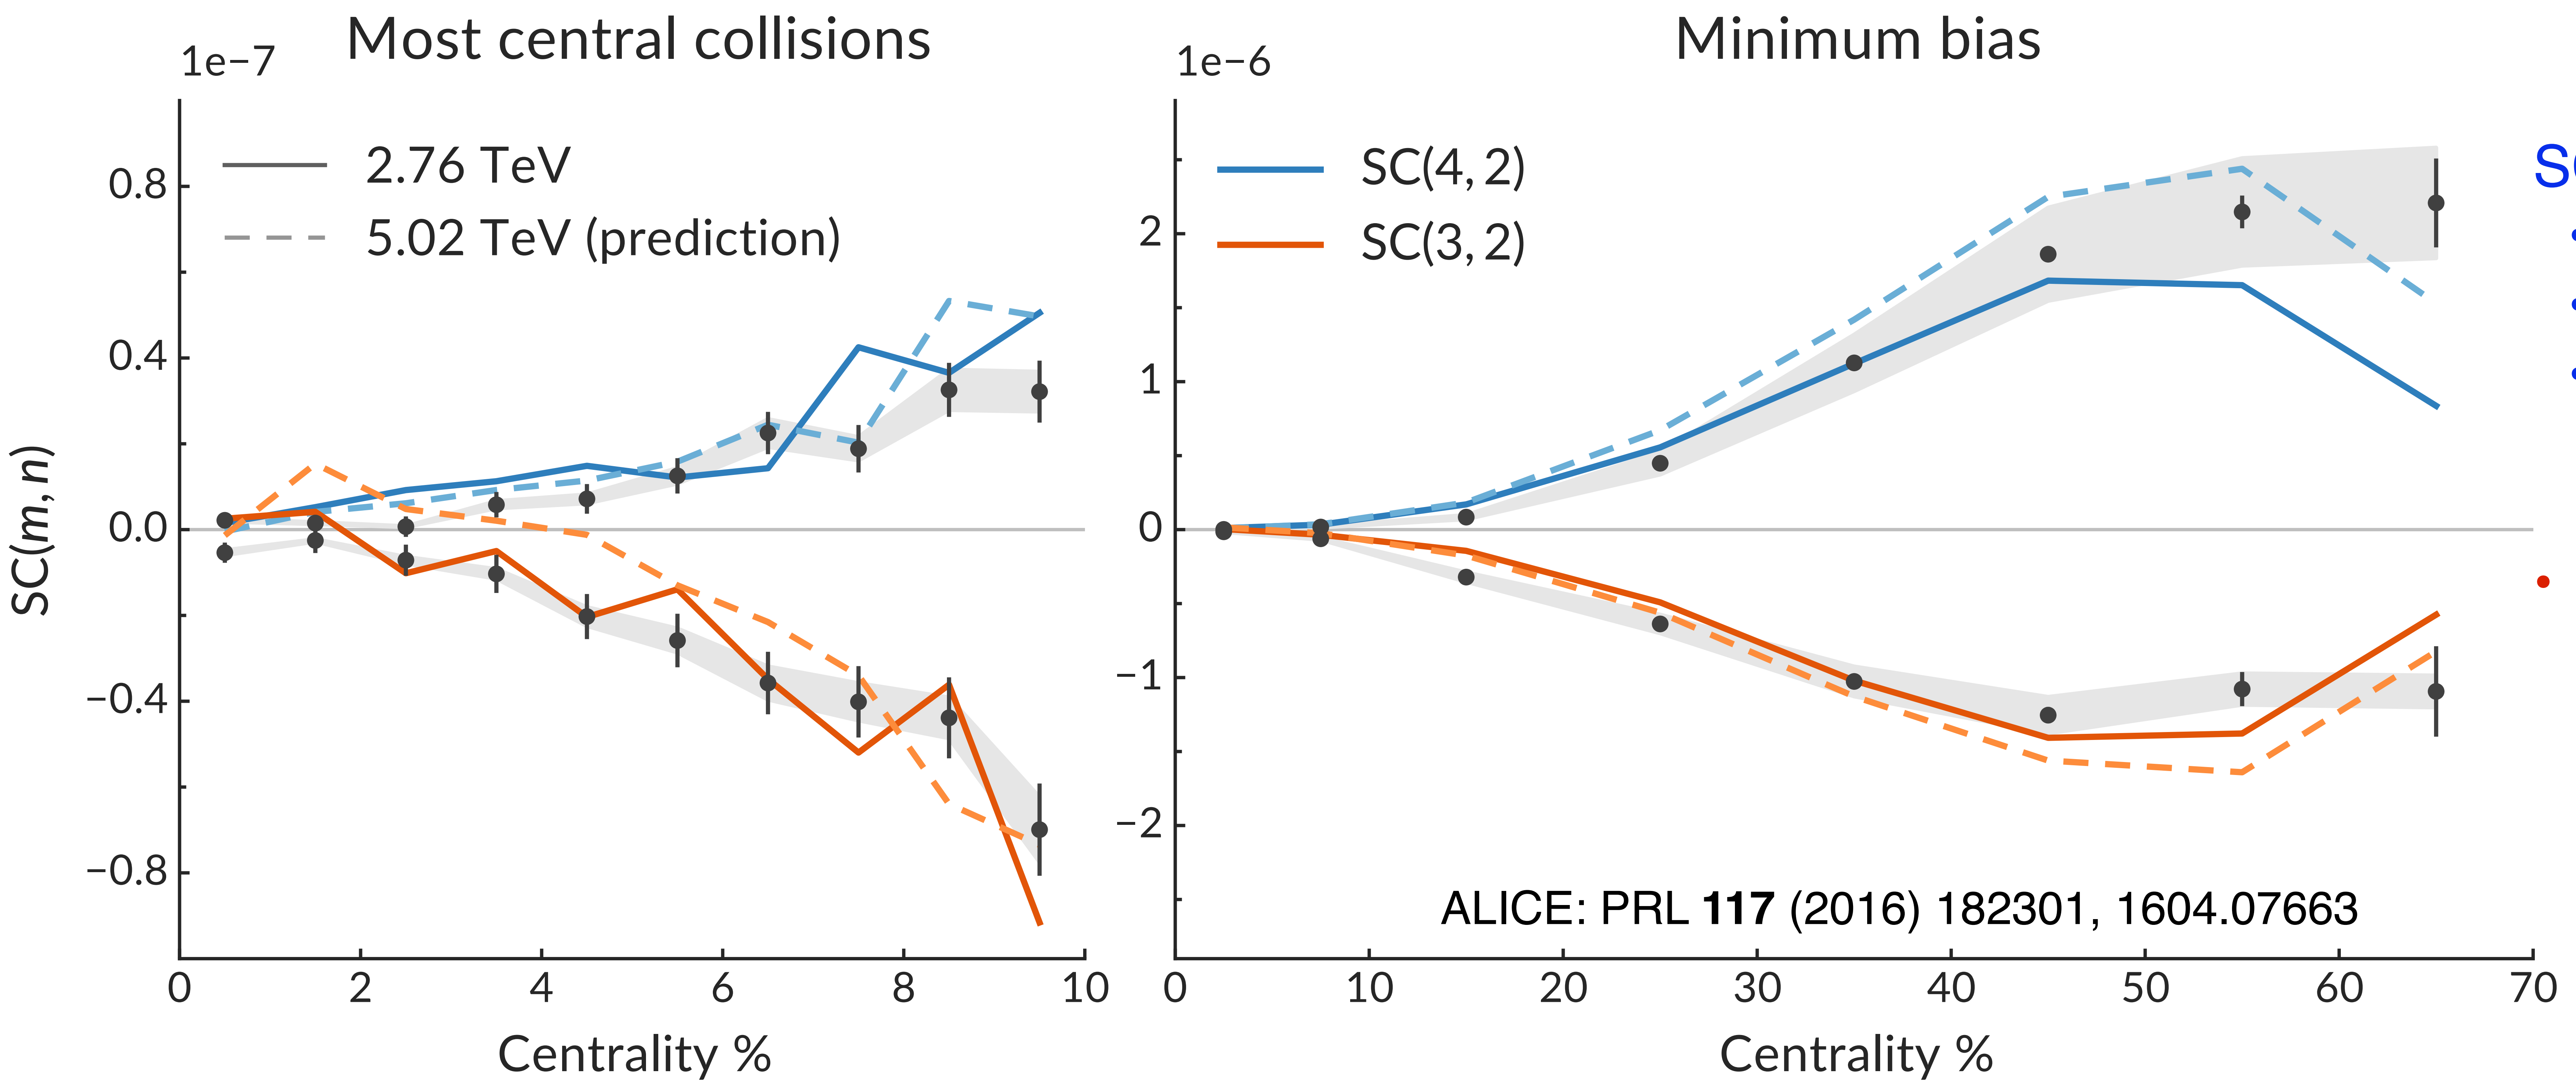
- description of data to within ±10% accuracy

Non-Calibrated Observables

The robustness and quality of the Physics Model can be tested by making predictions on observables not used during calibration using highest likelihood parameter values.

Example: correlations between event-by-event fluctuations of flow harmonics

$SC(m,n) = \langle v^2_m v^2_n \rangle - \langle v^2_m \rangle \langle v^2_n \rangle$



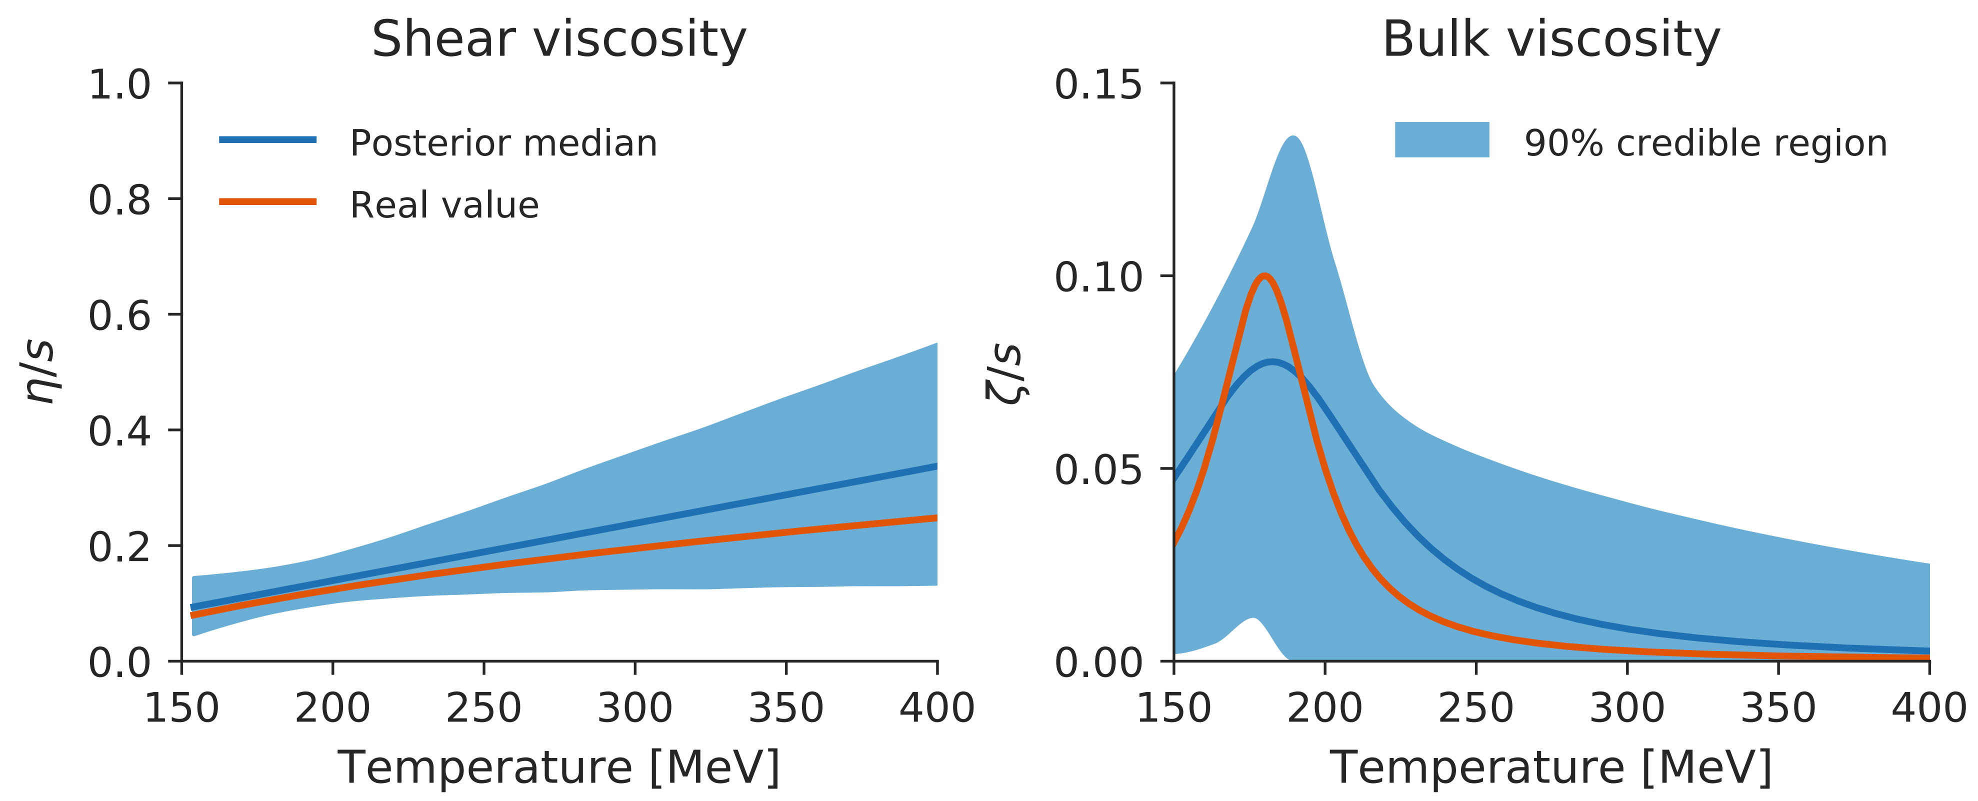
SC(m,n) are sensitive to:
- initial conditions
- evolution model
- QGP transport coefficients

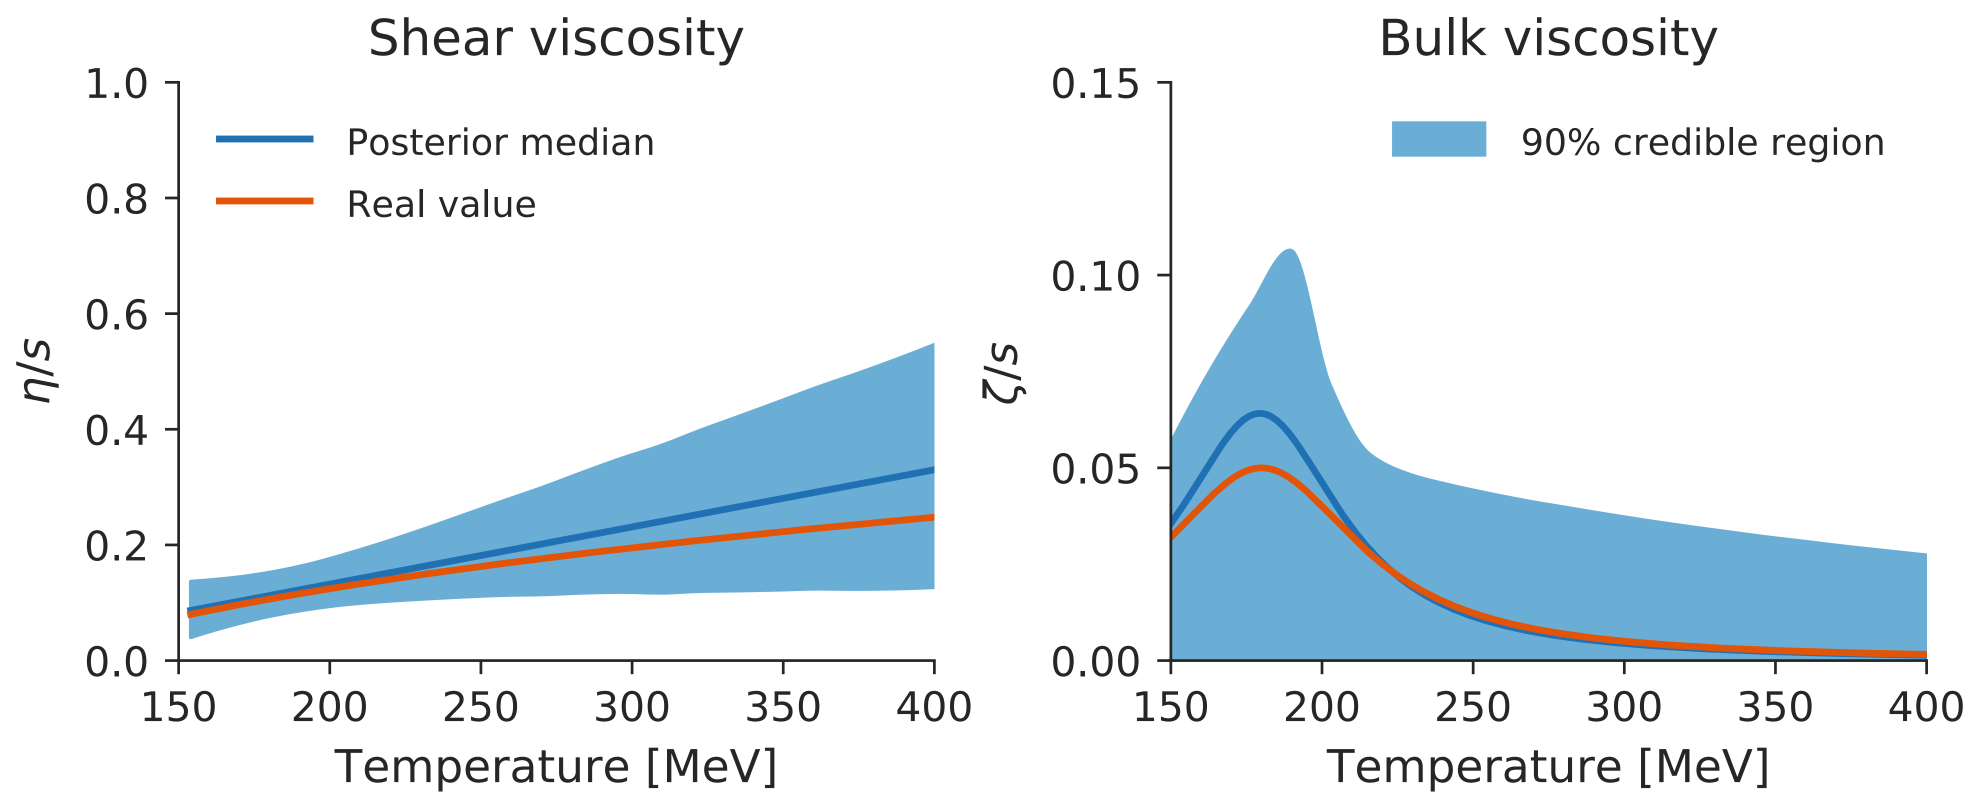
- excellent agreement of model prediction to data!

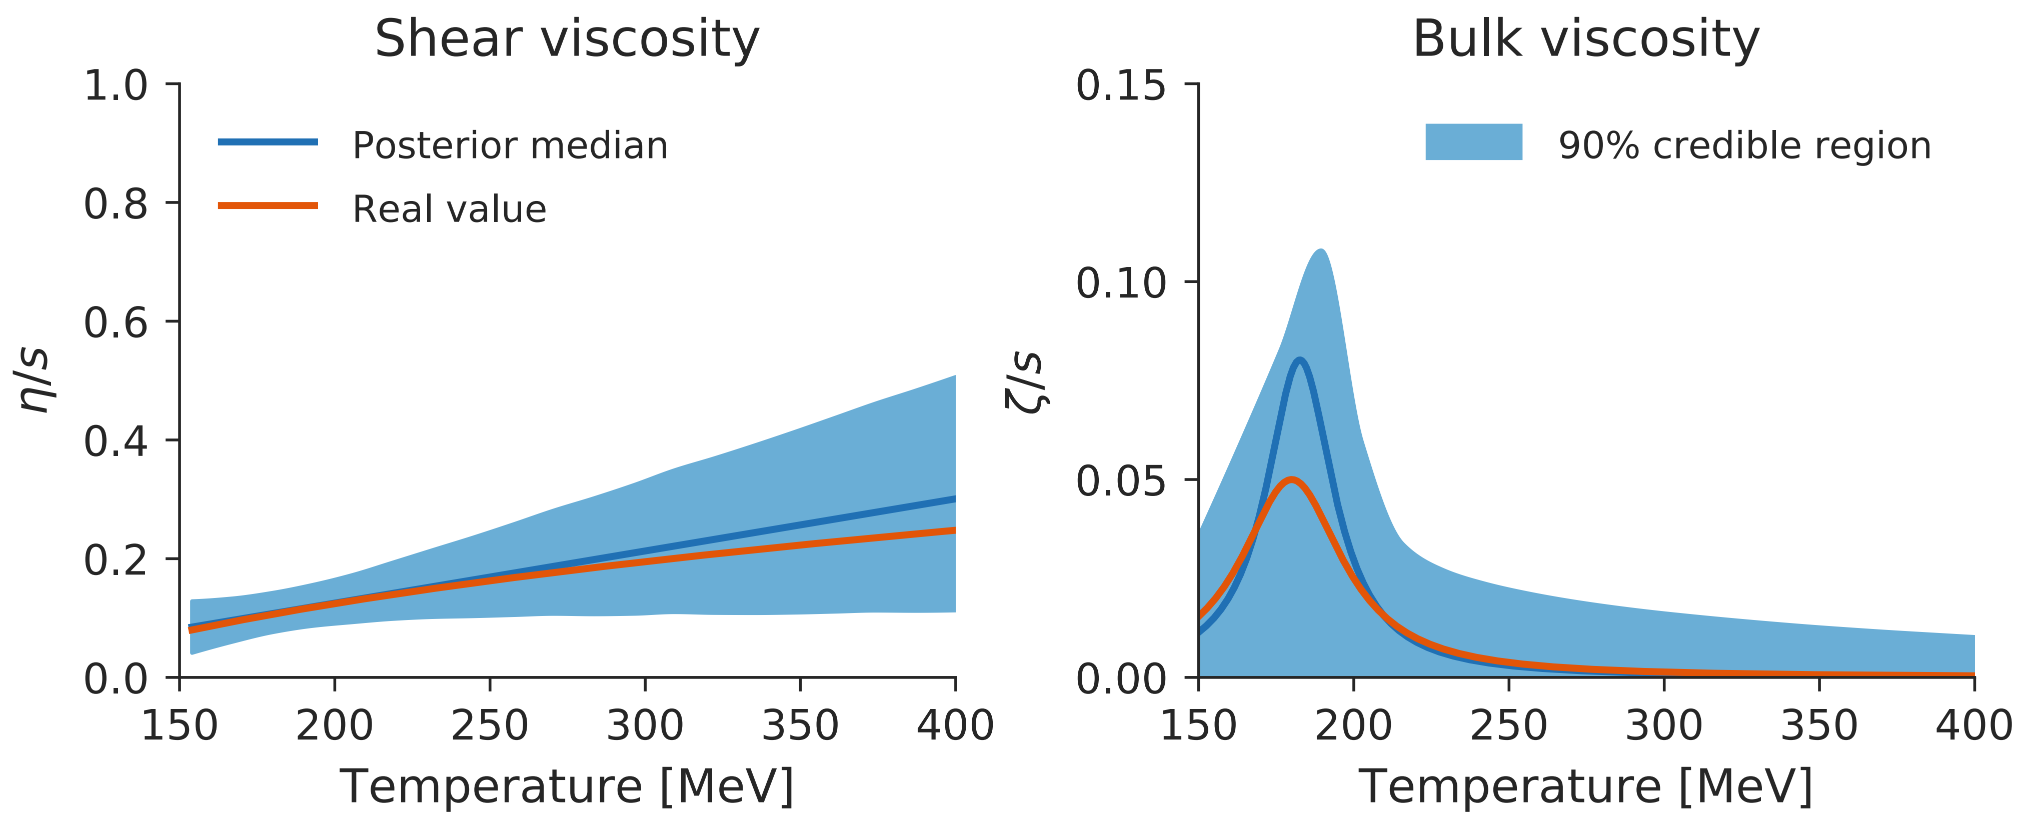
Closure Test

Need to verify that analysis can recover "true" values for the parameters: run physics model with chosen set of parameters, generate "fake data" from model output and then conduct analysis on that fake data to test if the input parameters can be recovered!

- both, smooth functions as well as peaked functions, can be reproduced well within the 90% CR
- note: due to reduction of information when going from model output to observables & model/GP uncertainties one should not expect a one-to-one reconstruction
- bulk analysis is mostly sensitive to area under bulk peak, not peak position, height & width independently



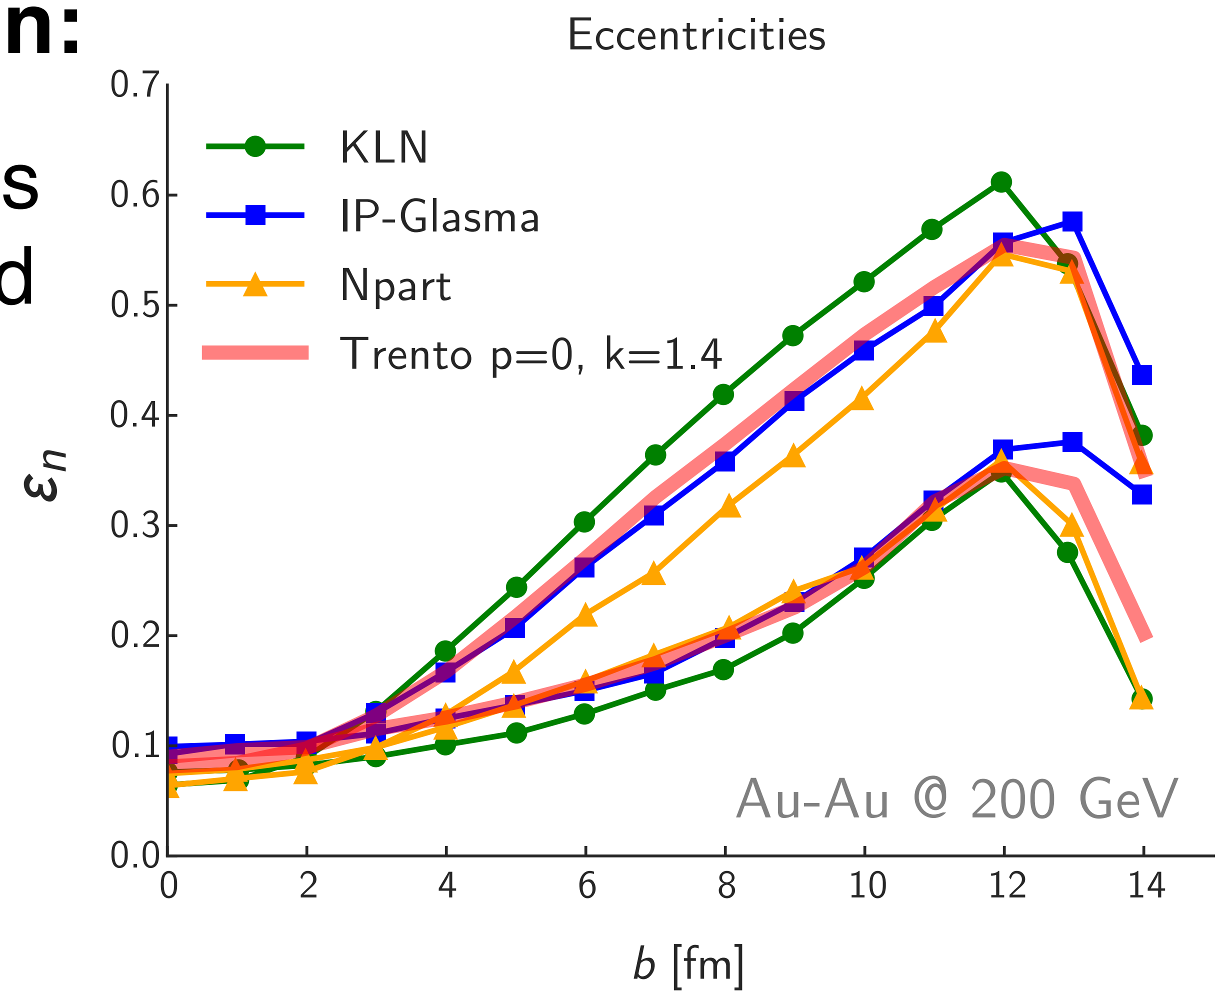




Summary I: Key Physics Results

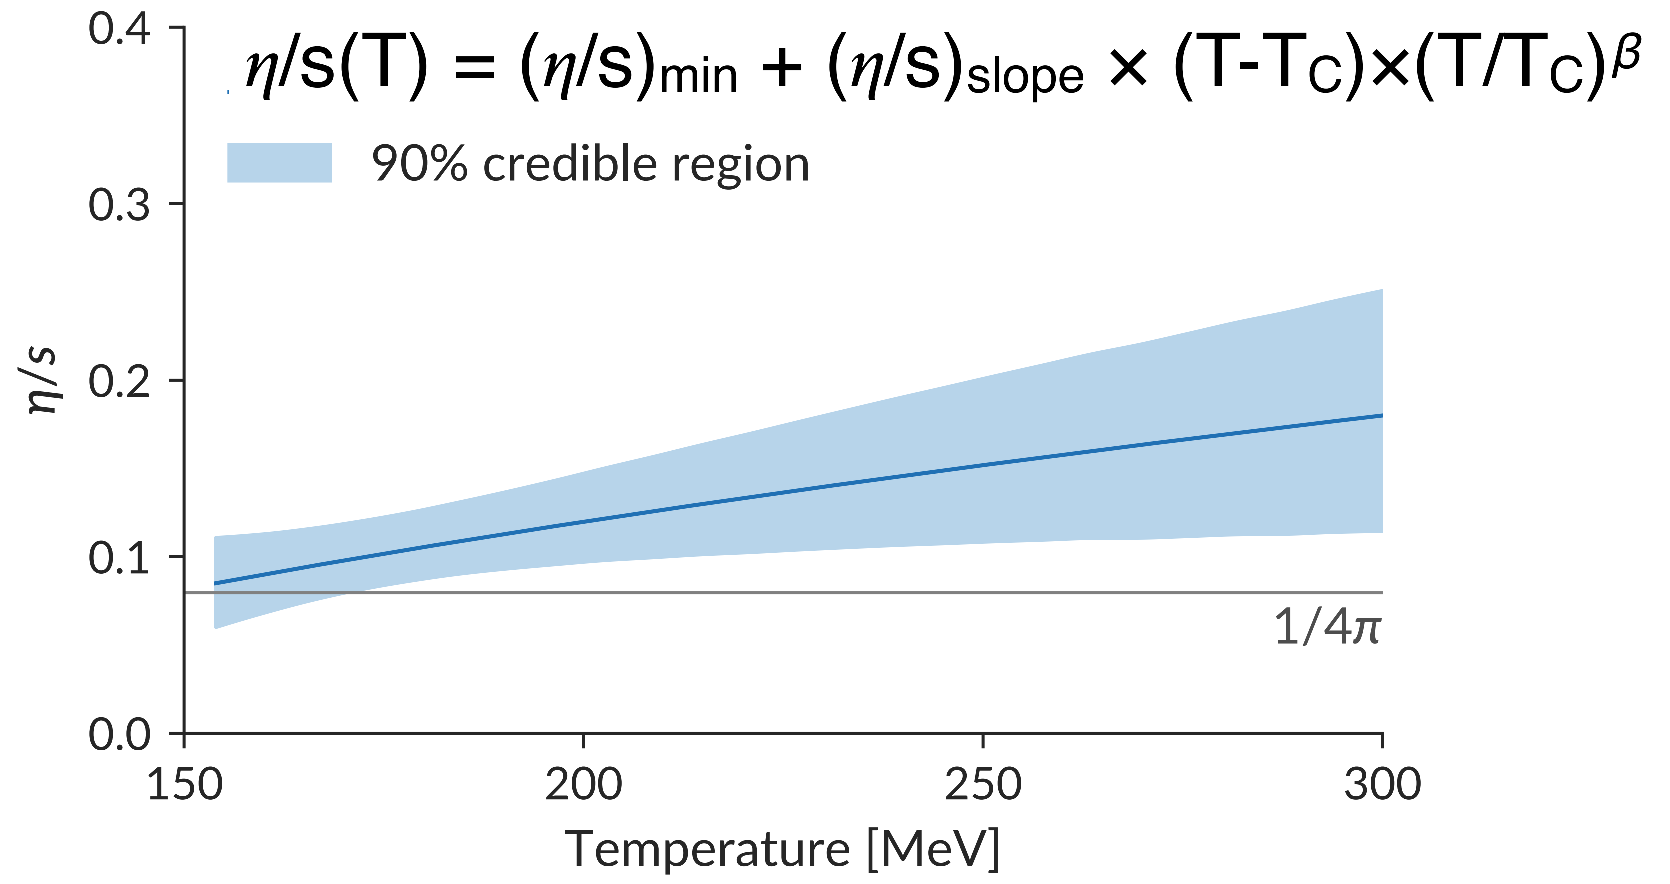
Trento initial condition:

- analysis strongly favors eccentricity scaling and entropy deposition of EKRT & IP-Glasma model
- Glauber and KLN models strongly disfavored



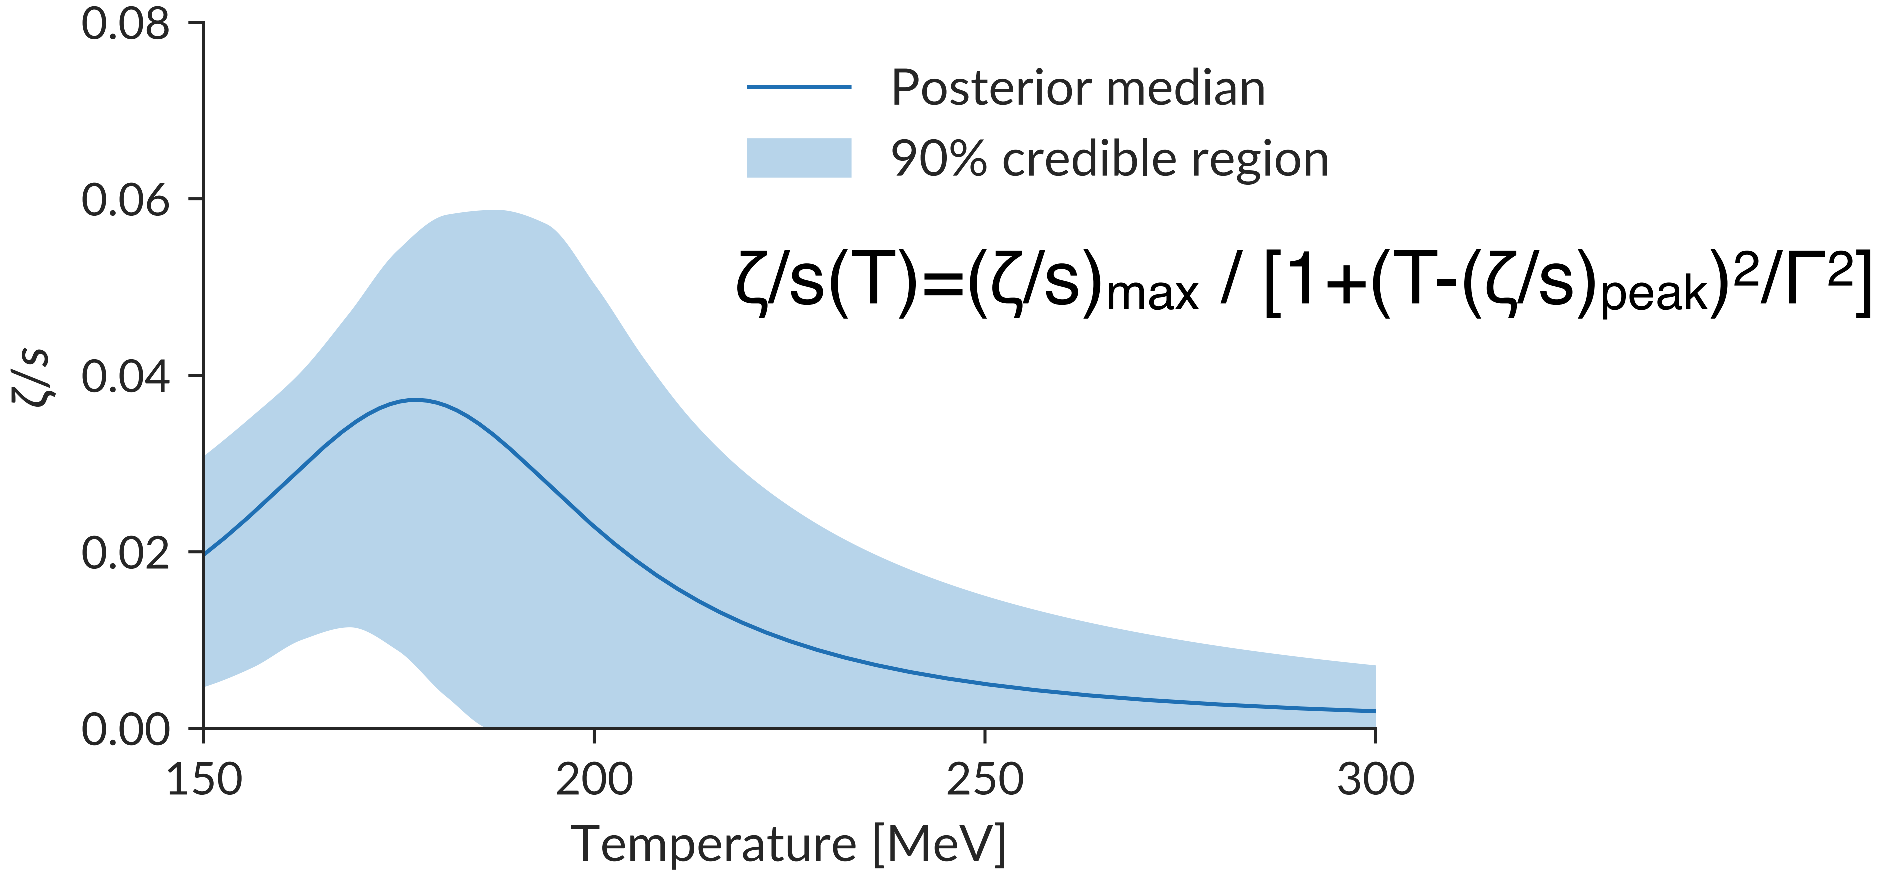
temperature dependent shear viscosity:

- analysis favors small value and shallow rise
- slope vs. curvature needs disambiguation



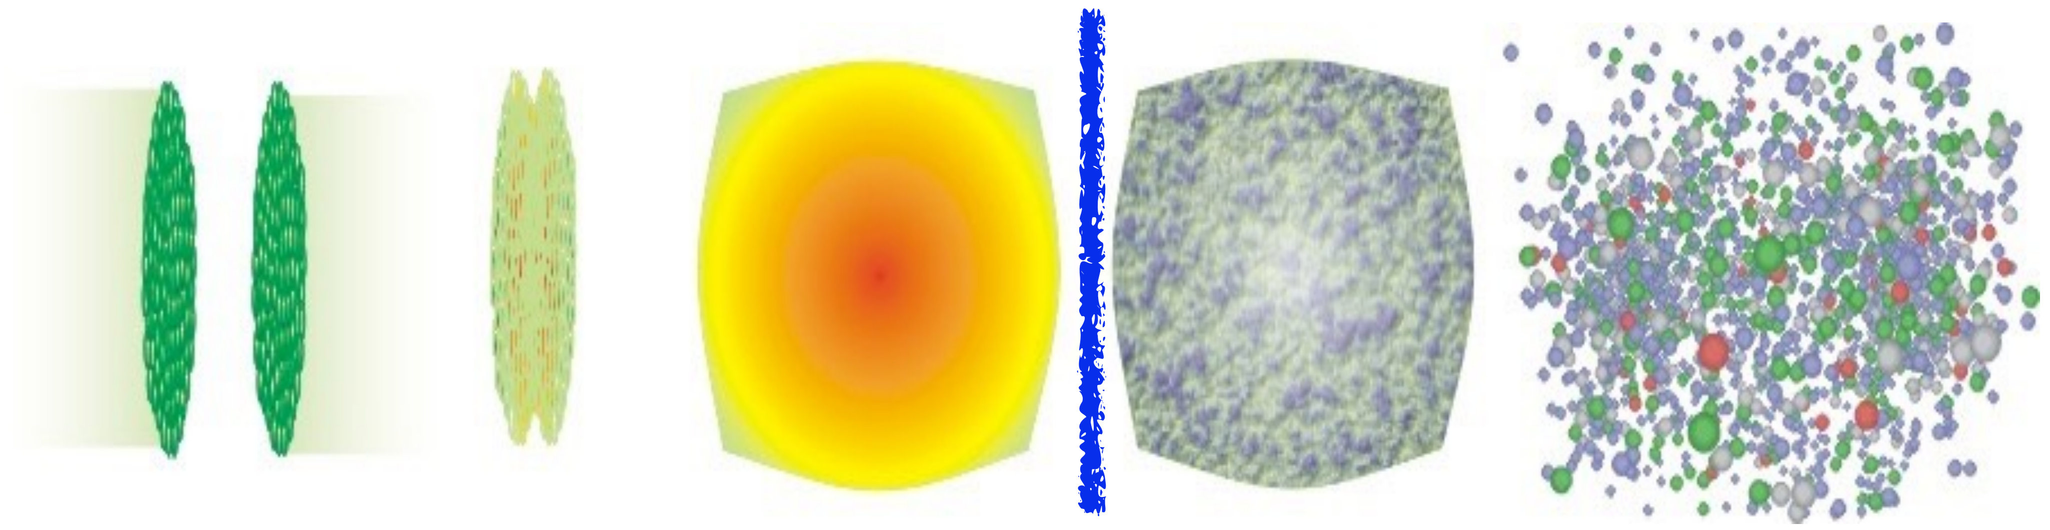
temperature dependent bulk viscosity:

- non-zero value near T_C favored
- ambiguities exist for peak hight vs. width

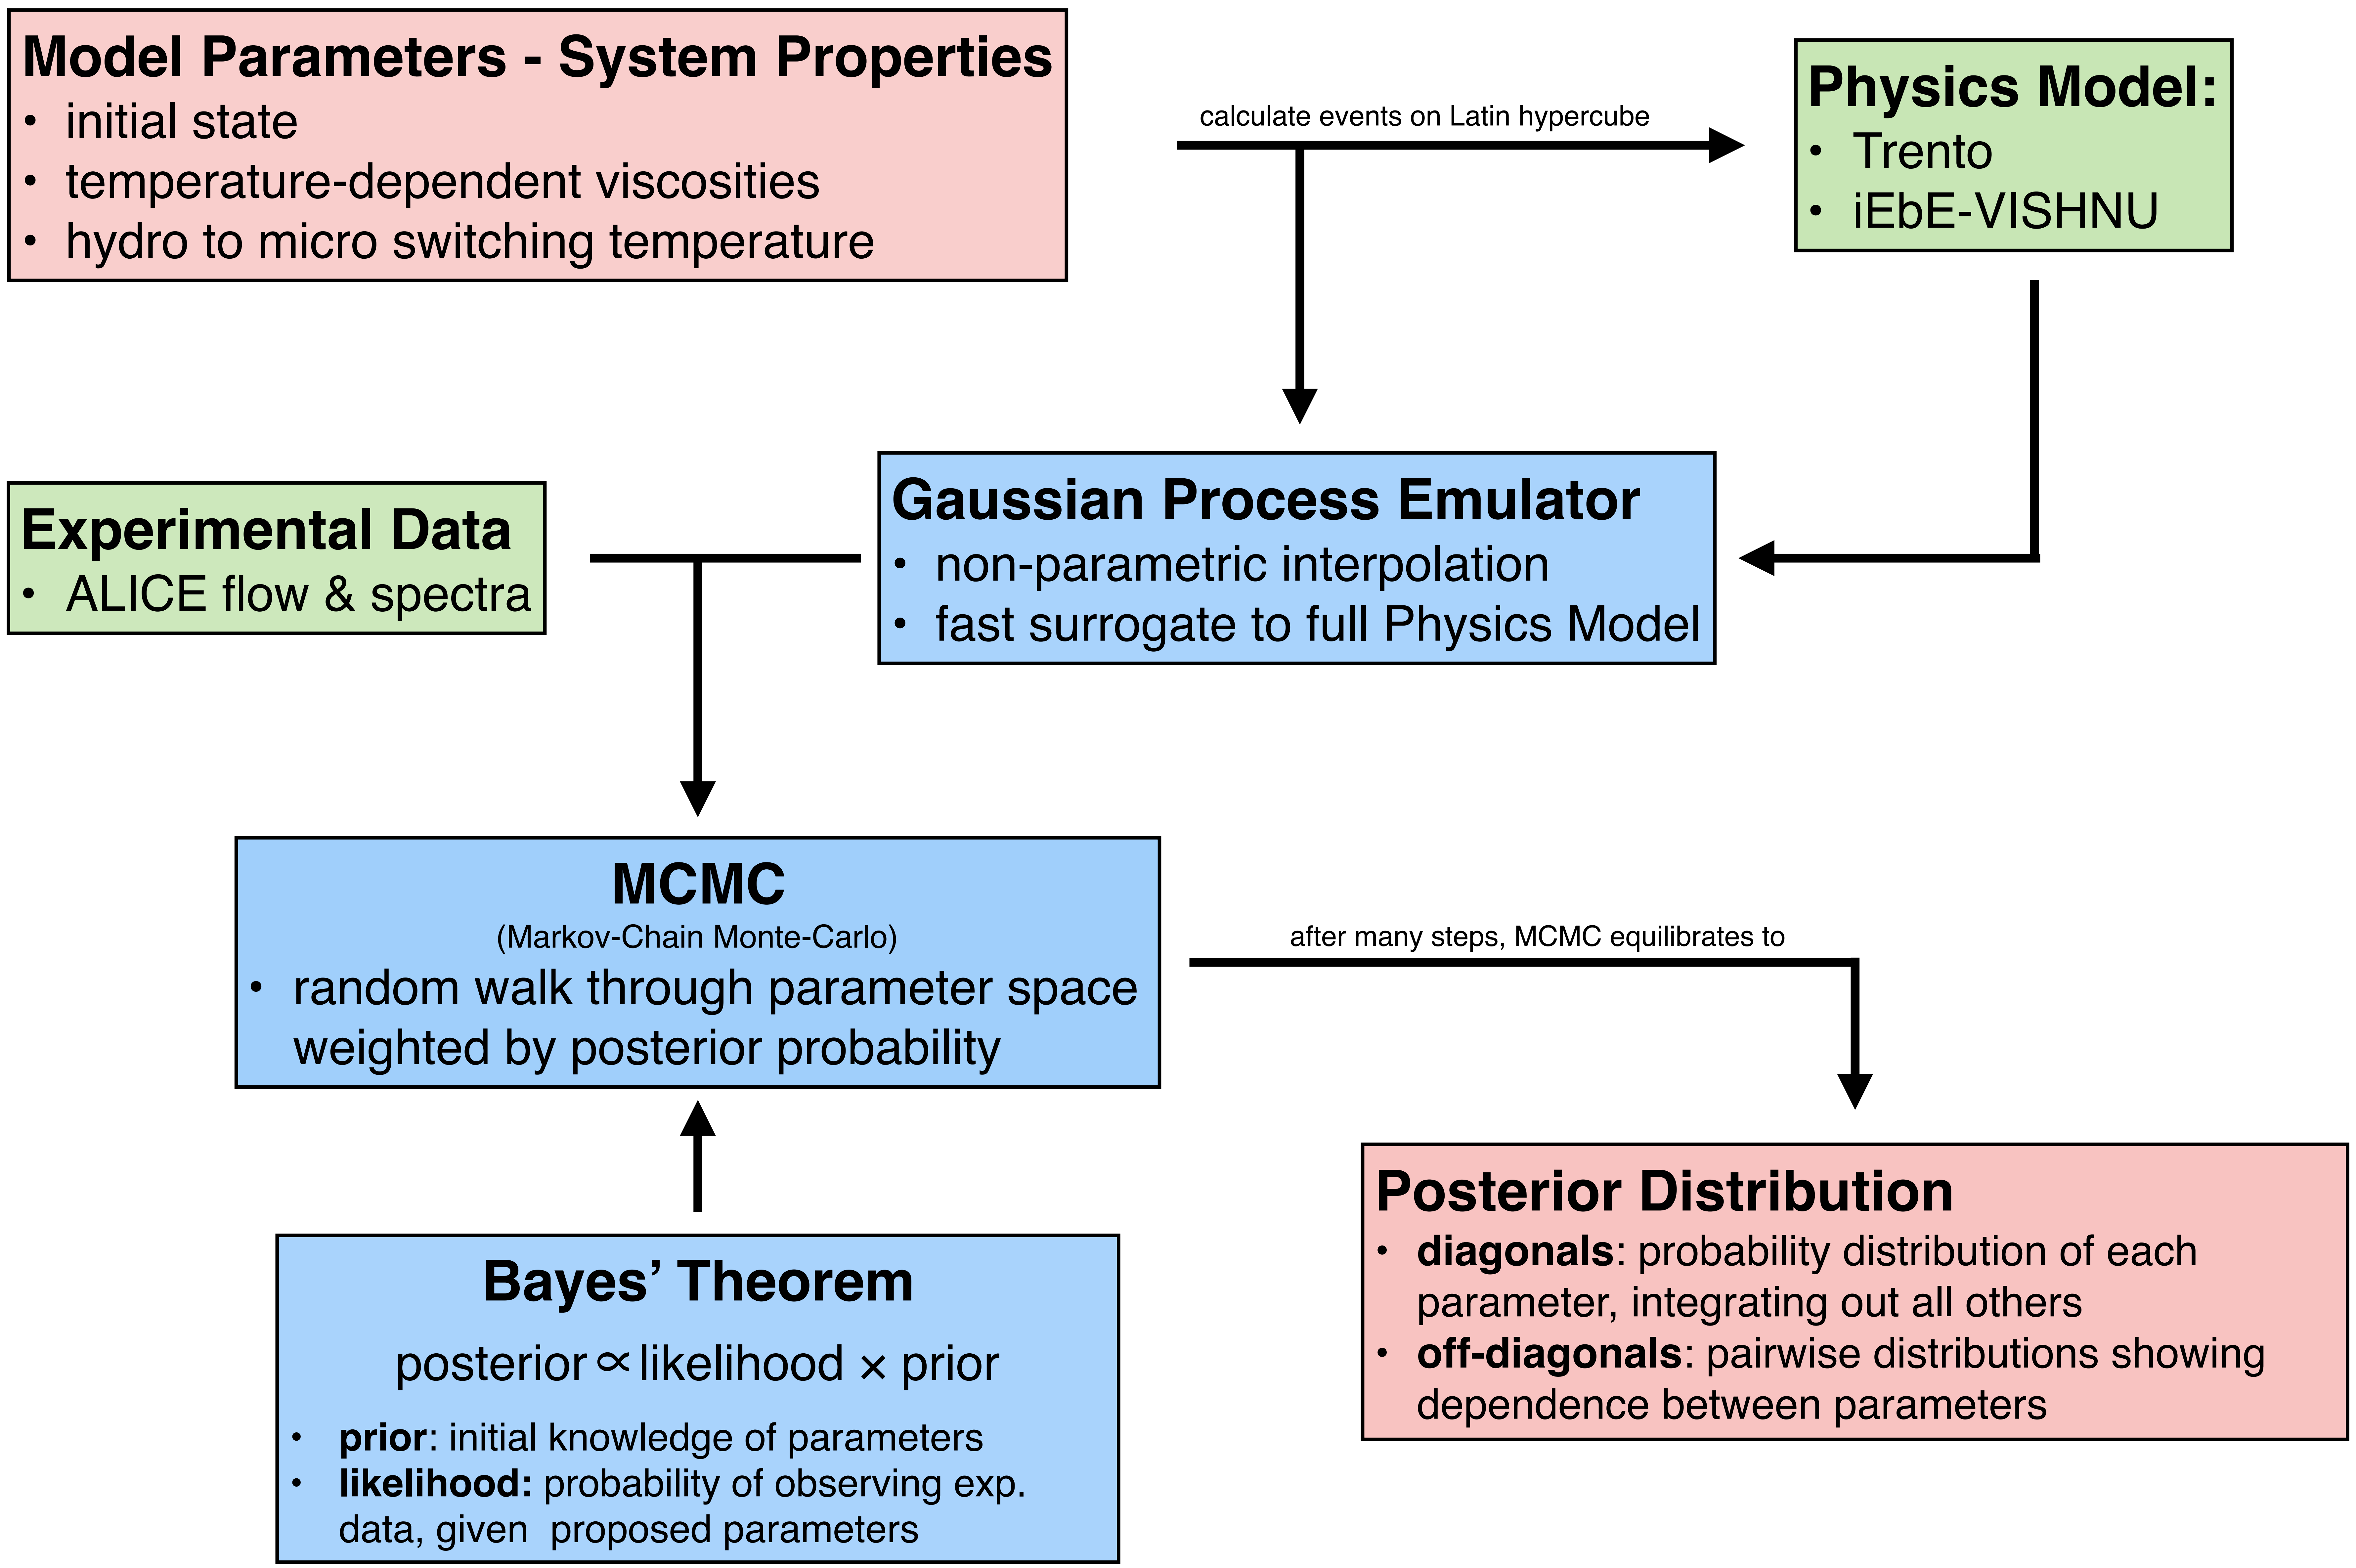


hydro to micro switching temperature T_{sw}

- strong likelihood for a value of T_{sw} just around T_C
- indicative of the non-equilibrium nature and dynamical breakup of the hadronic system



Summary II: Methodology



Outlook & Future Directions

current analysis focus was on the properties of bulk QCD matter and utilized only LHC data on soft hadrons. The analysis needs to be extended to:

- **include data from lower beam energies**
  - necessary for determination of the temperature and μ_B dependence of transport coefficients
- **include asymmetric collision systems (p+A, d+A, 3He+A, A+B)**
  - generate improved understanding of the initial state
- **include hard probes (jets and heavy quark observables)**
  - consistent determination of jet and heavy flavor transport coefficients

JETSCAPE

- **include other physics models**
  - analysis is model agnostic, allows for quantitative comparison among different models and verification/falsification of models/conceptual approaches

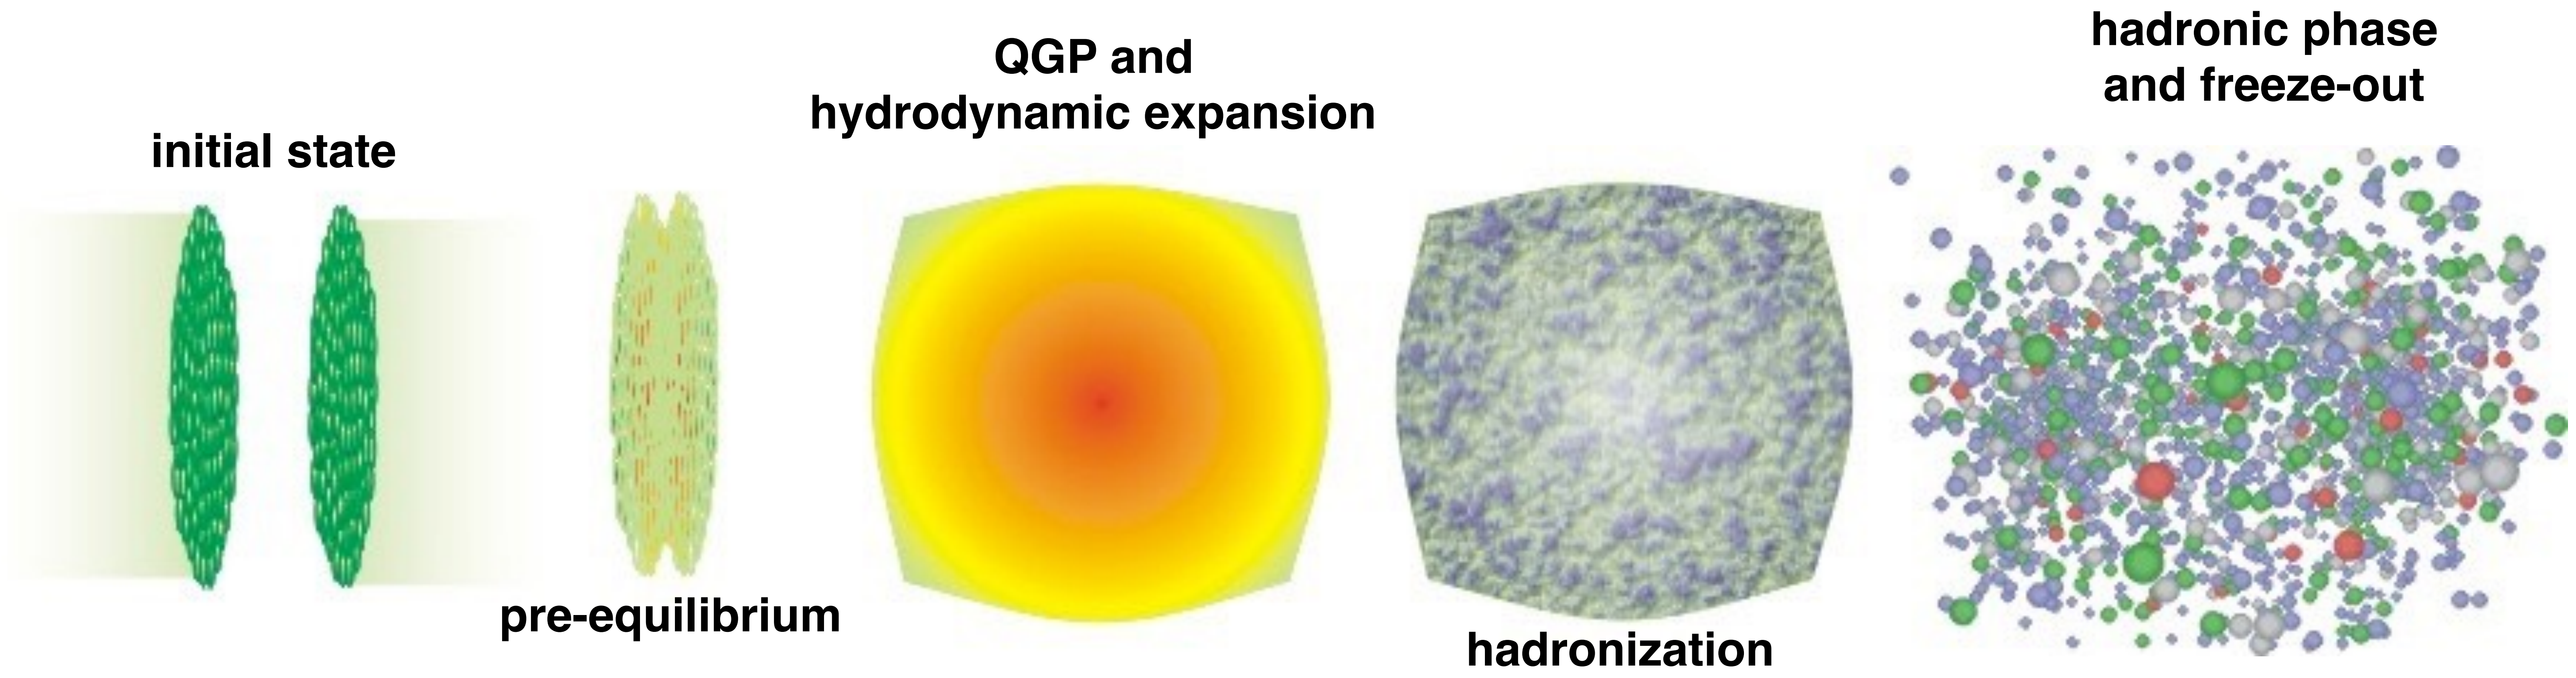
The End

Time Evolution of a Heavy-Ion Collision



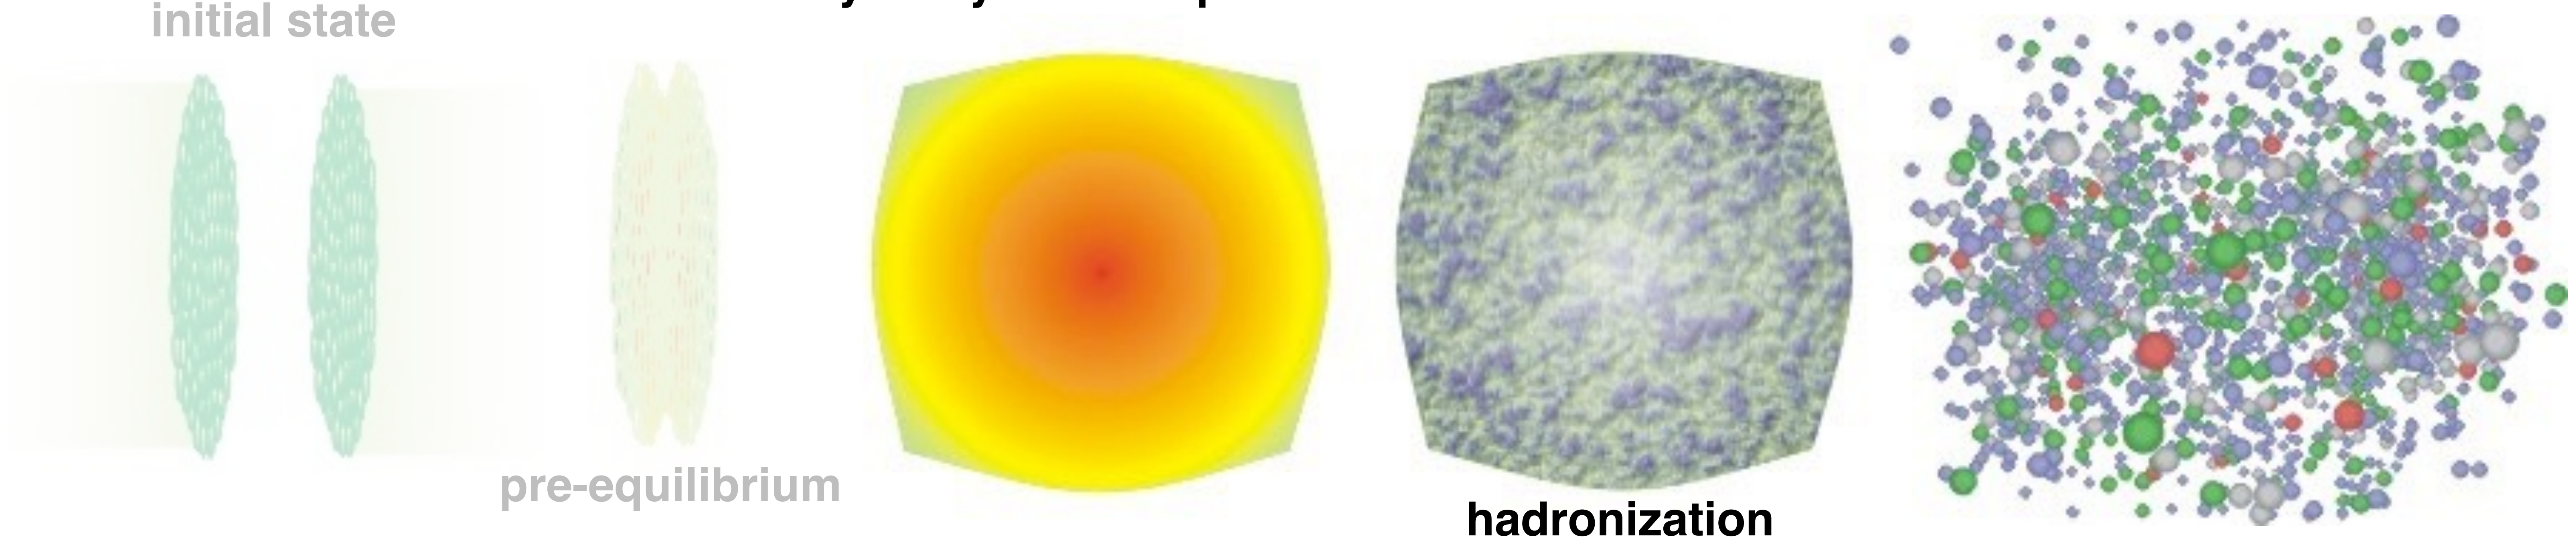
- **Initial State:**
  - fluctuates event-by-event
  - classical color-field dynamics

- **QGP and hydrodynamic expansion:**
  - proceeds via 3D viscous RFD
  - EoS from Lattice QCD

- **Pre-equilibrium:**
  - rapid change-over from glue-field dominated initial state to thermalized QGP
  - time scale: 0.15 to 2 fm/c in duration
  - build-up of transverse velocity fields?

- **hadronic phase & freeze-out**
  - interacting hadron gas
  - separation of chemical and kinetic freeze-out

Constraining the IS of Heavy-Ion Collisions

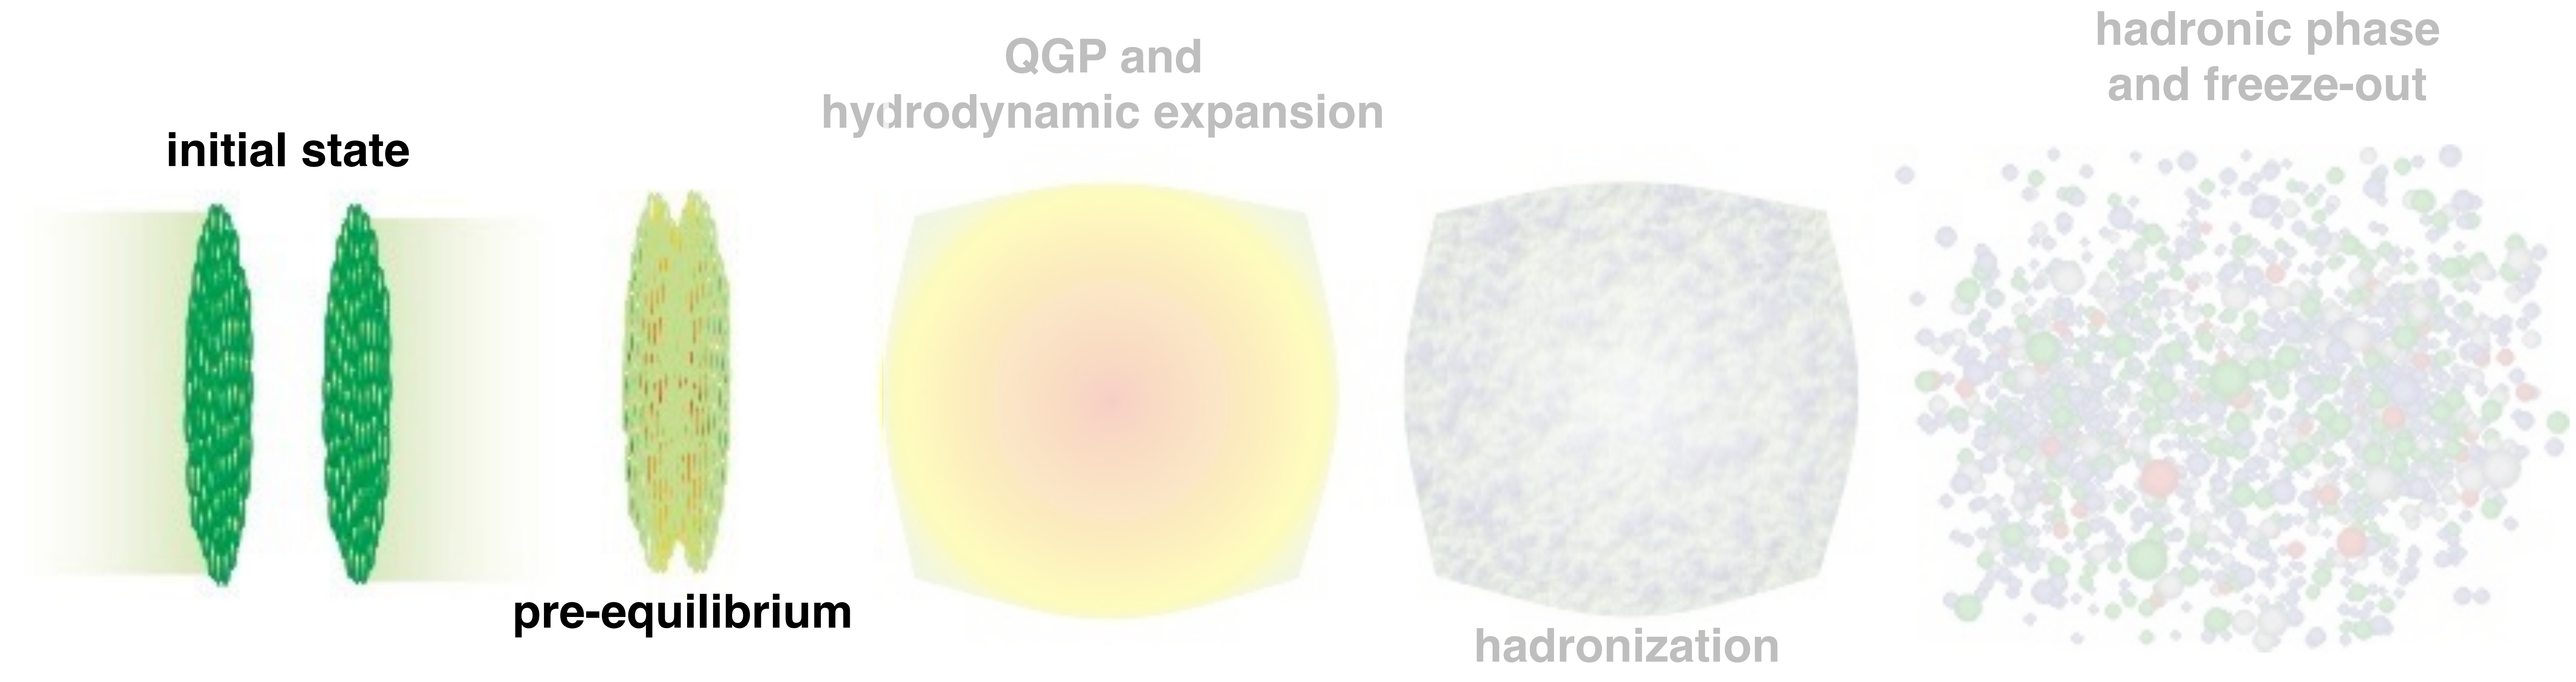


- treatment of QGP evolution and hadronic freeze-out is well established and largely understood
- major success: first extraction of QGP properties such as η/s
- major challenges:
  - quantify uncertainties in extracted QGP properties
  - temperature dependence of transport coefficients

- **QGP and hydrodynamic expansion:**
  - proceeds via 3D viscous RFD
  - EoS from Lattice QCD

- **hadronic phase & freeze-out**
  - interacting hadron gas
  - separation of chemical and kinetic freeze-out

Constraining the IS of Heavy-Ion Collisions

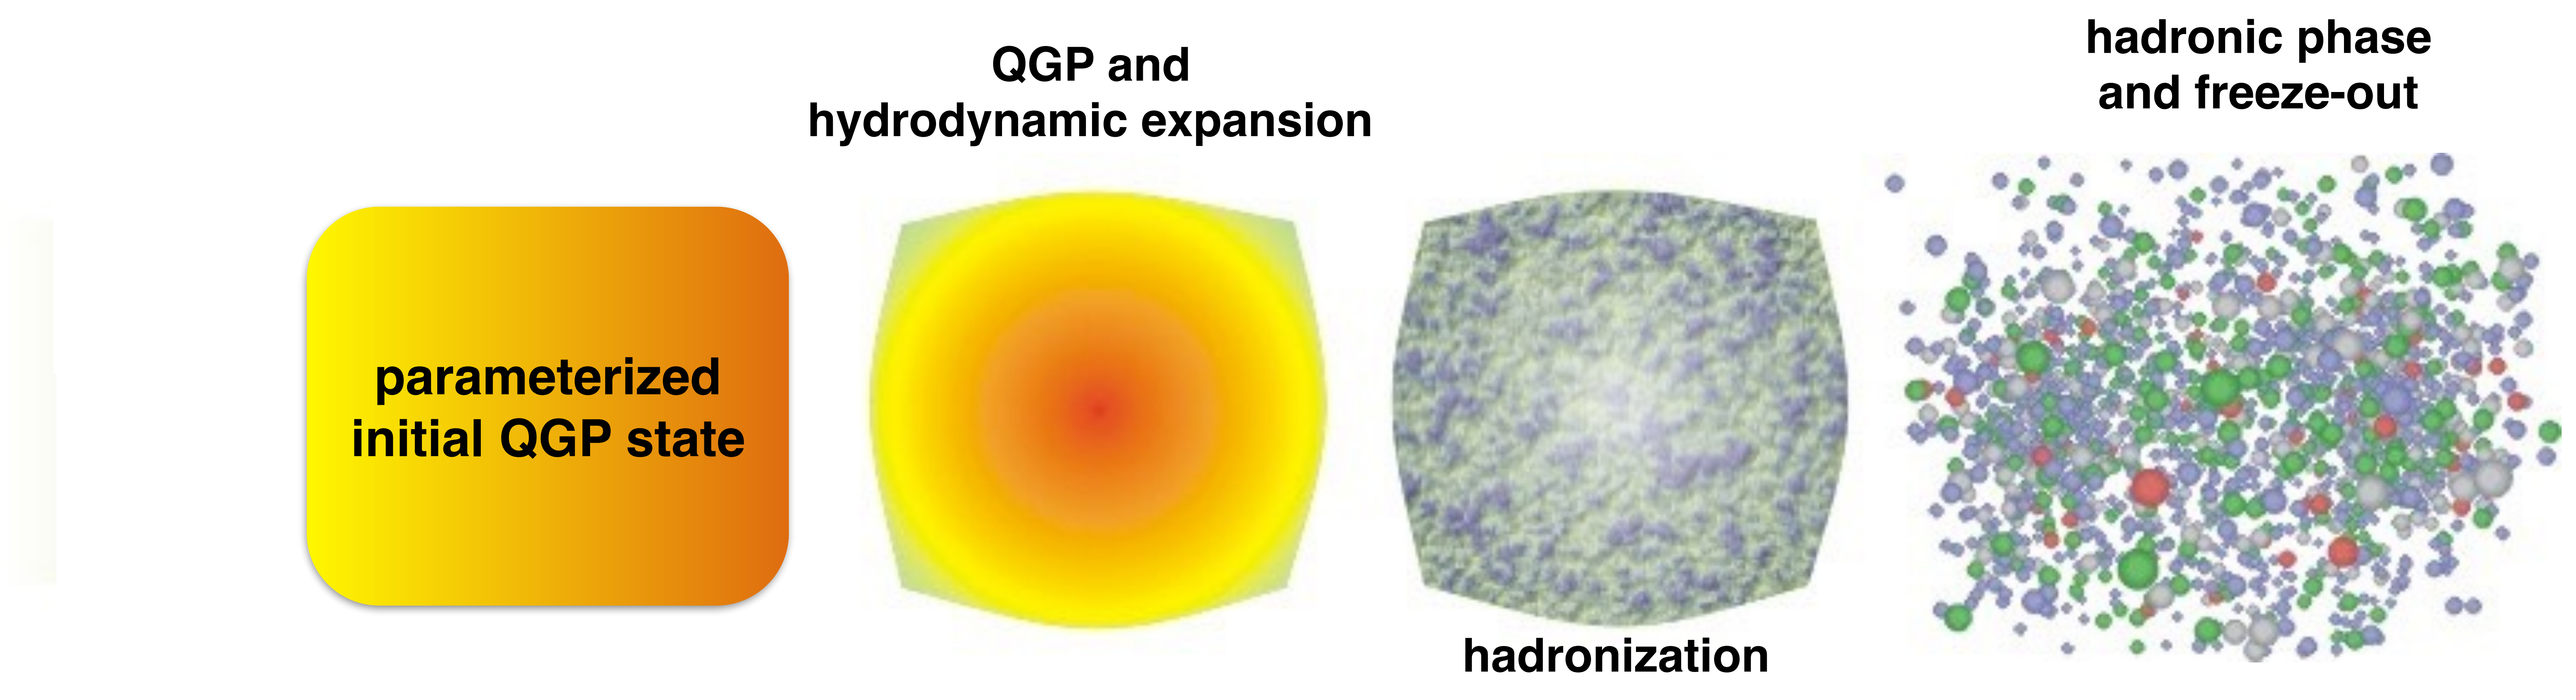


- **Initial State:**
  - fluctuates event-by-event
  - classical color-field dynamics

- **Pre-equilibrium:**
  - rapid change-over from glue-field dominated initial state to thermalized QGP
  - time scale: 0.15 to 2 fm/c in duration
  - build-up of transverse velocity fields?

- physics of initial state and pre-equilibrium dynamics are still conceptually challenging with many open questions
  - what processes drive the system towards equilibration?
  - on what timescale?
  - …
- **a major source of uncertainty for the extraction of QGP properties**

Constraining the IS of Heavy-Ion Collisions



parameterized initial QGP state:

- based on simple phenomenological ideas for entropy deposition
- constrained by global model to data fit
- provides guidance to ab-initio IS models on features needed to describe the data

- **QGP and hydrodynamic expansion:**
  - proceeds via 3D viscous RFD
  - EoS from Lattice QCD

- **hadronic phase & freeze-out**
  - interacting hadron gas
  - separation of chemical and kinetic freeze-out

Initial Condition Model: Trento

- effective, parametric, description of entropy production prior to thermalization
- based on **reduced thickness* T_R** as ansatz for *dS/dy*:

$$dS/dy\,|_{\tau=\tau_0} \propto T_R(p;T_A,T_B) \equiv \left(\frac{T_A^p + T_B^p}{2}\right)^{1/p}$$

- determine participant nucleons in A, B by sampling for each nucleon pair:

$$P_{\rm coll} = 1 - \exp\left[-\sigma_{gg}\int dx\,dy \int dz\,\rho_A \int dz\,\rho_B\right]$$

Nuclear Thickness*:

$$T_A = \sum_i \gamma_i \int dz\,\rho_{\rm nucleon}(x-x_i, y-y_i, z-z_i)$$

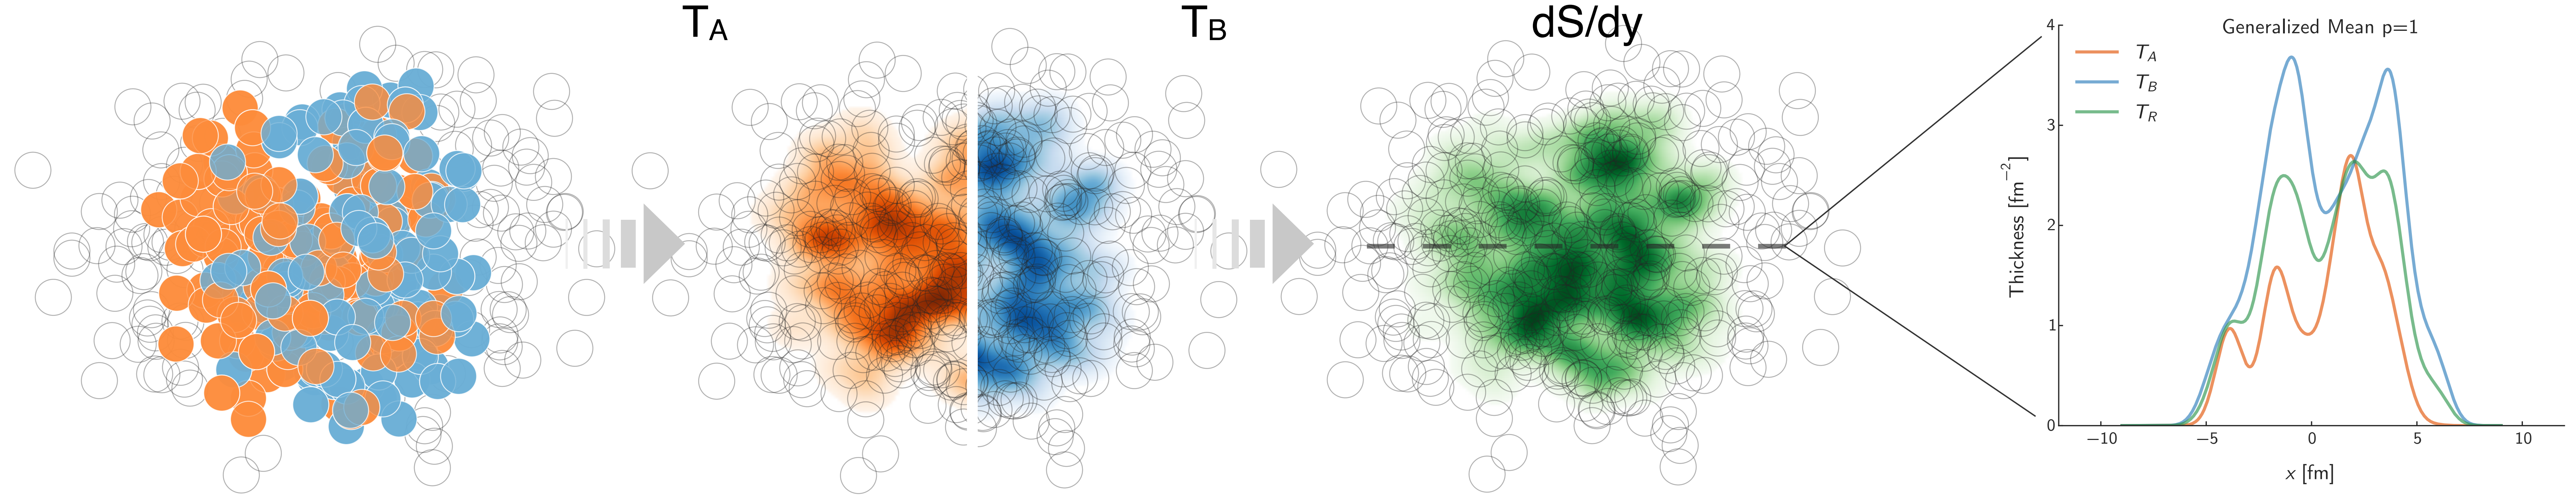
- sum is over participant nucleons with positions sampled from an uncorrelated Woods-Saxon distribution or correlated nuclear configurations when available
- introduce fluctuations via γ_i, sampled from a gamma distribution with unit mean:

$$P_k(\gamma) = \frac{k^k}{\Gamma(k)}\gamma^{k-1}e^{-k\gamma}$$

- nucleon density $\rho_{\rm nucleon}$ modeled as Gaussian in transverse plane

$$\int dz\,\rho_{\rm proton} = \frac{1}{2\pi w^2}\exp\left(-\frac{x^2+y^2}{2w^2}\right)$$

(1) determine participants: **(2) construct thickness functions:** **(3) calculate entropy deposition:**

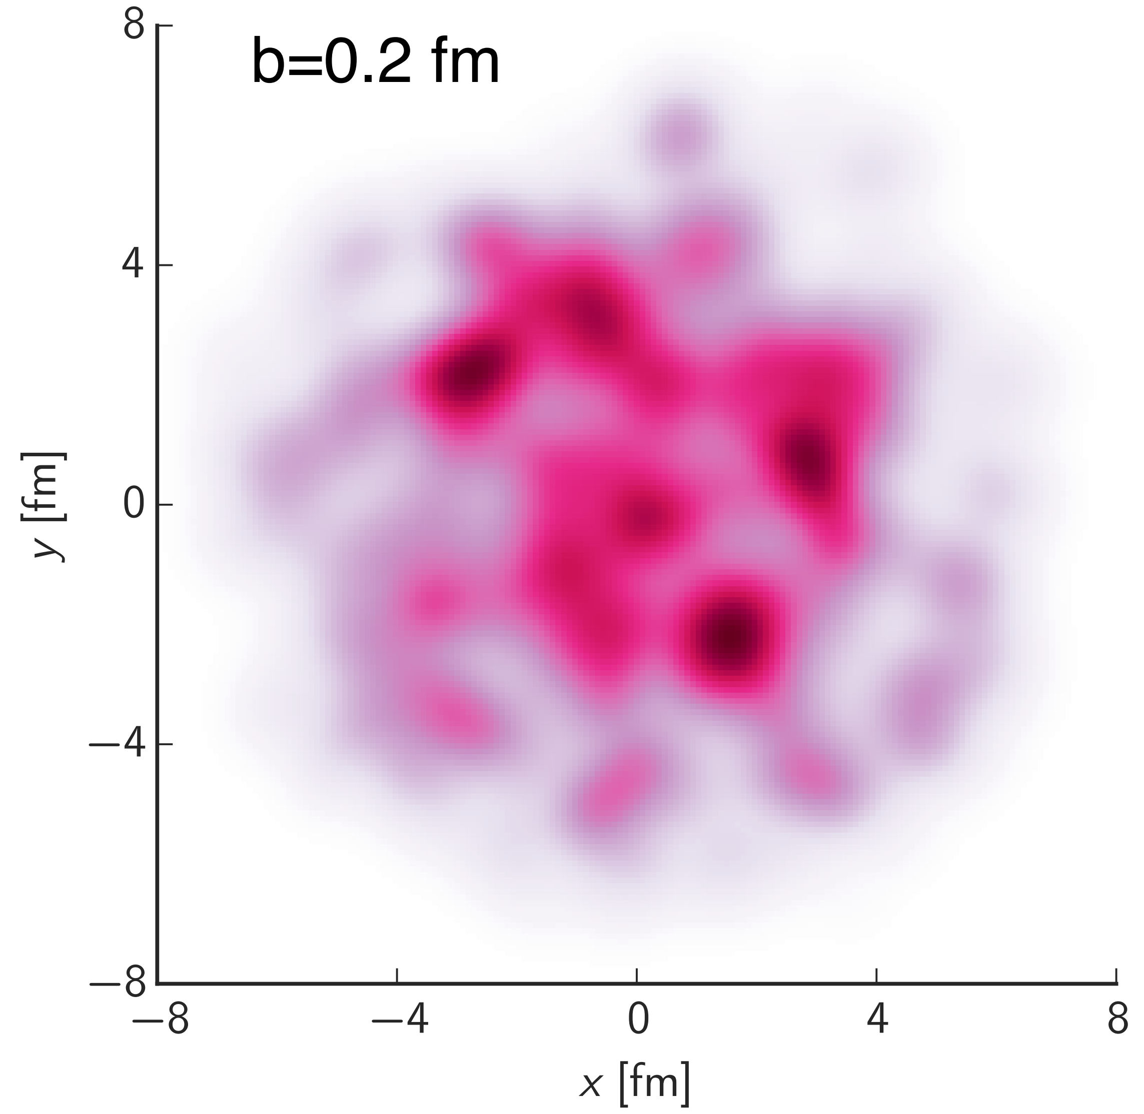


model parameters:

- attenuation parameter: p
- fluctuation parameter: k
- width of nucleon: w
- overall normalization: C_{norm}

model output:

- event by event spatial entropy density distribution at mid-rapidity at thermalization time τ_0



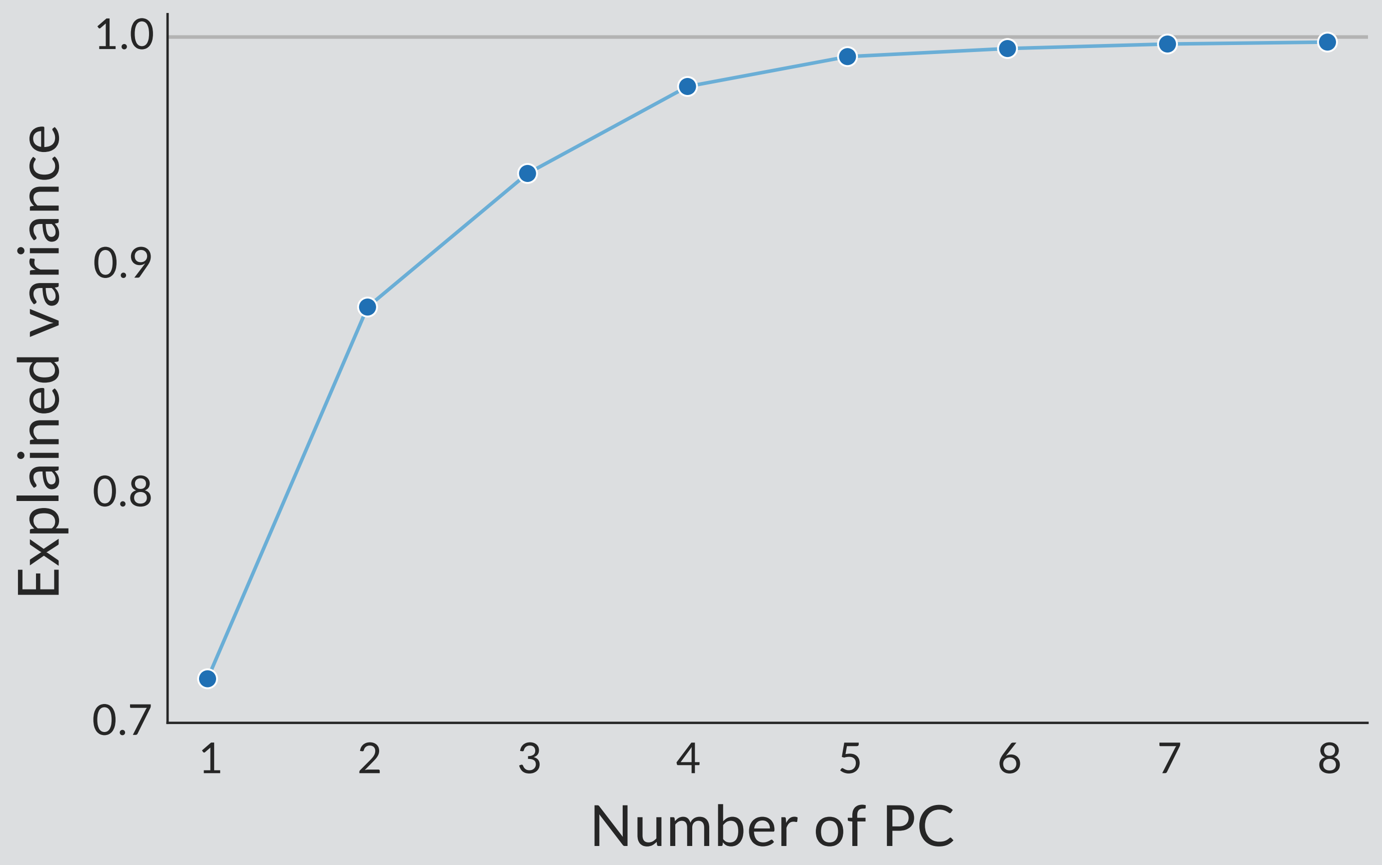
Multivariate Output

Scaling of analysis with # of observables:

- independent emulators for each output?
  - neglects correlations among outputs
  - what if # of outputs scales to 100?
  - ▸ training of individual GPE's may become unfeasible and unnecessary in case of strong correlations

this analysis:

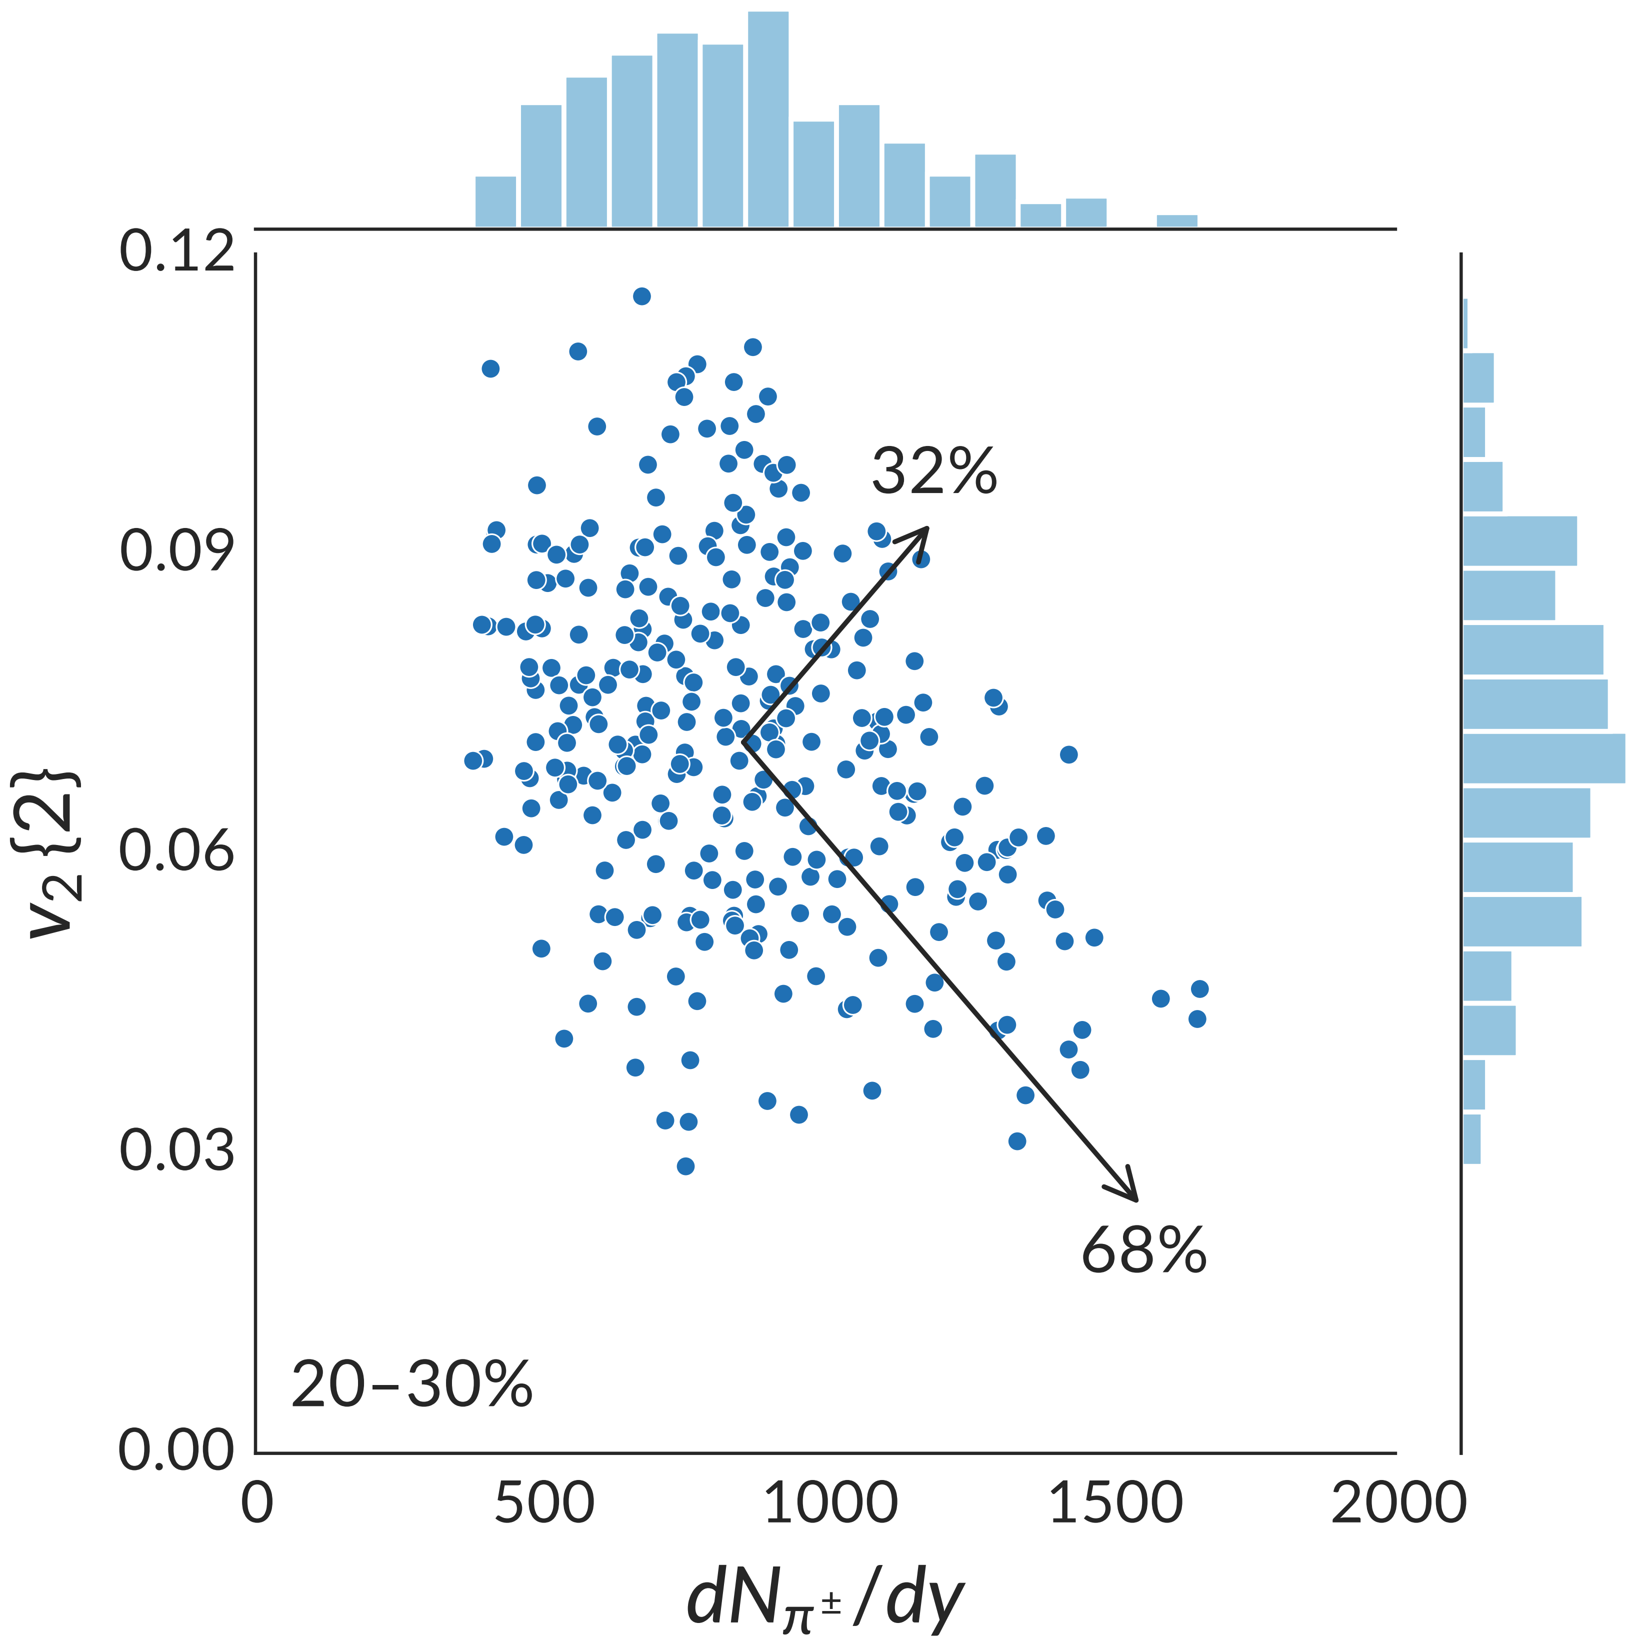
- model outputs are yields, $\langle p_T \rangle$, v_2, v_3 and v_4
- 68 original output dimensions
- 8 principal components used



Principal Components:

- linear combinations of model output
- orthogonal and uncorrelated

⇒ emulate each PC



Next steps:

- **sub-nucleon degrees of freedom**
- **forward/backward rapidity**

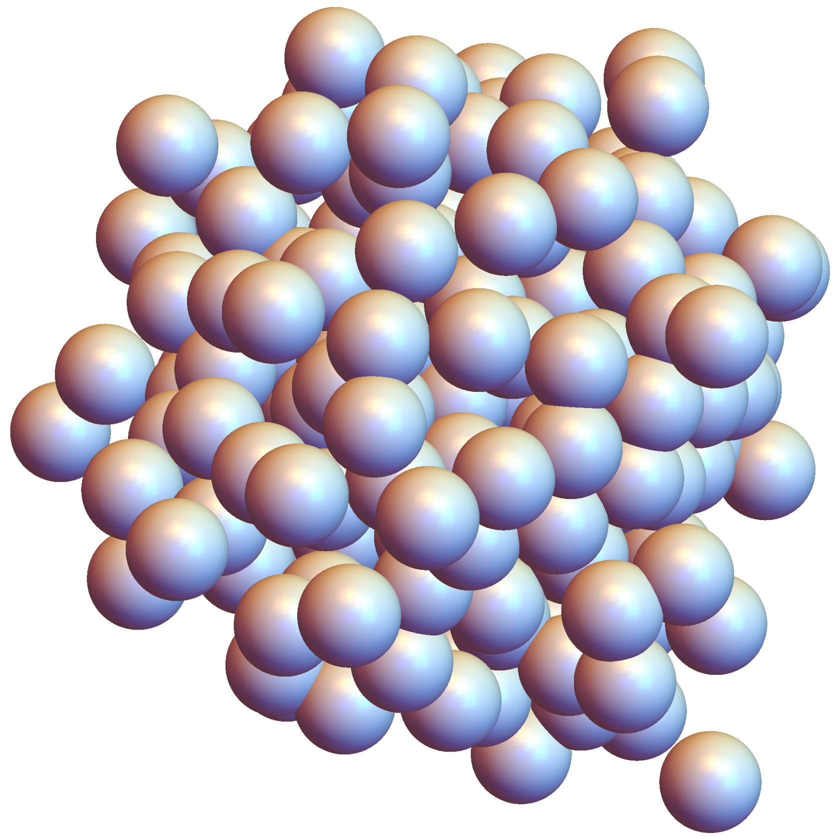
W. Ke, J.S. Moreland, J.E. Bernhard & S.A. Bass: Phys. Rev. **C96** (2017) 044912, arXiv:1610.08490
J.S. Moreland, J.E. Bernhard & S.A. Bass, arXiv1808.02106

Nucleon Substructure

Original Trento model:

- sample nucleon positions from spherical or deformed Woods-Saxon distributions
- solid angles resampled to preserve minimum distance d_{min}
- Gaussian nucleons of width w
- works very well for large nuclei

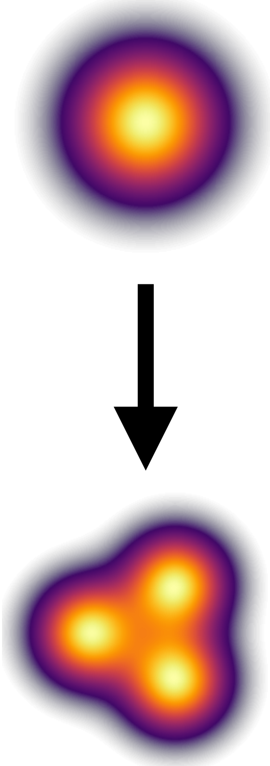
^{208}Pb nucleus



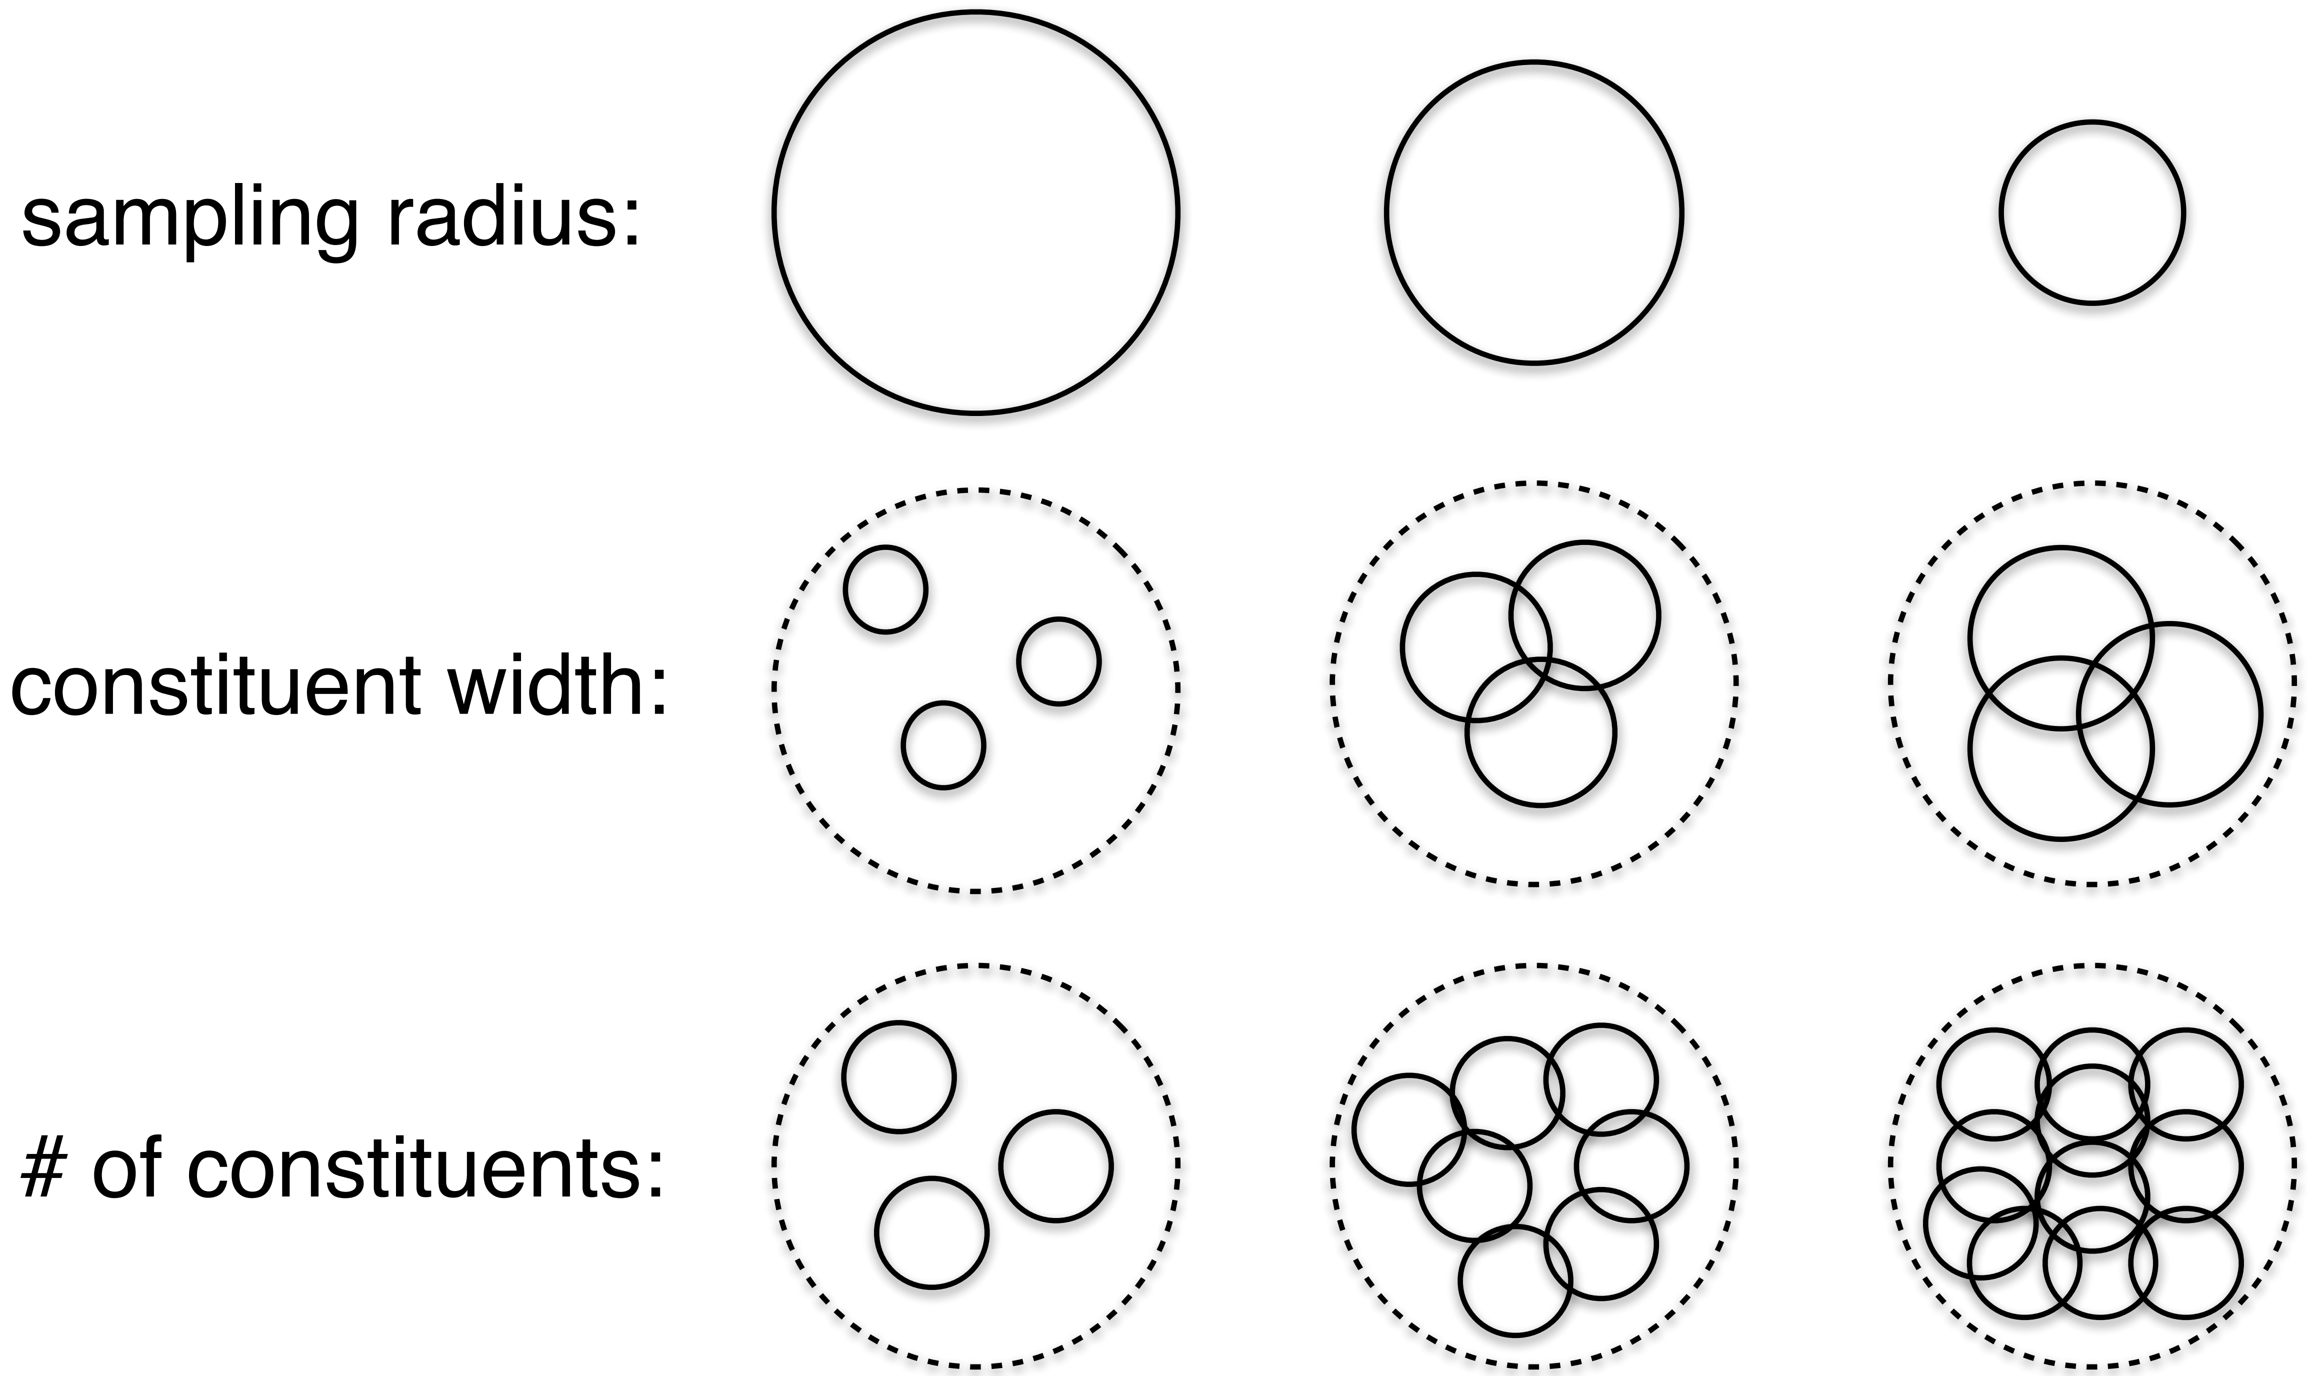
Caveat:

- spherical protons do not allow for proper eccentricities in p+A or small/asymmetric collision systems

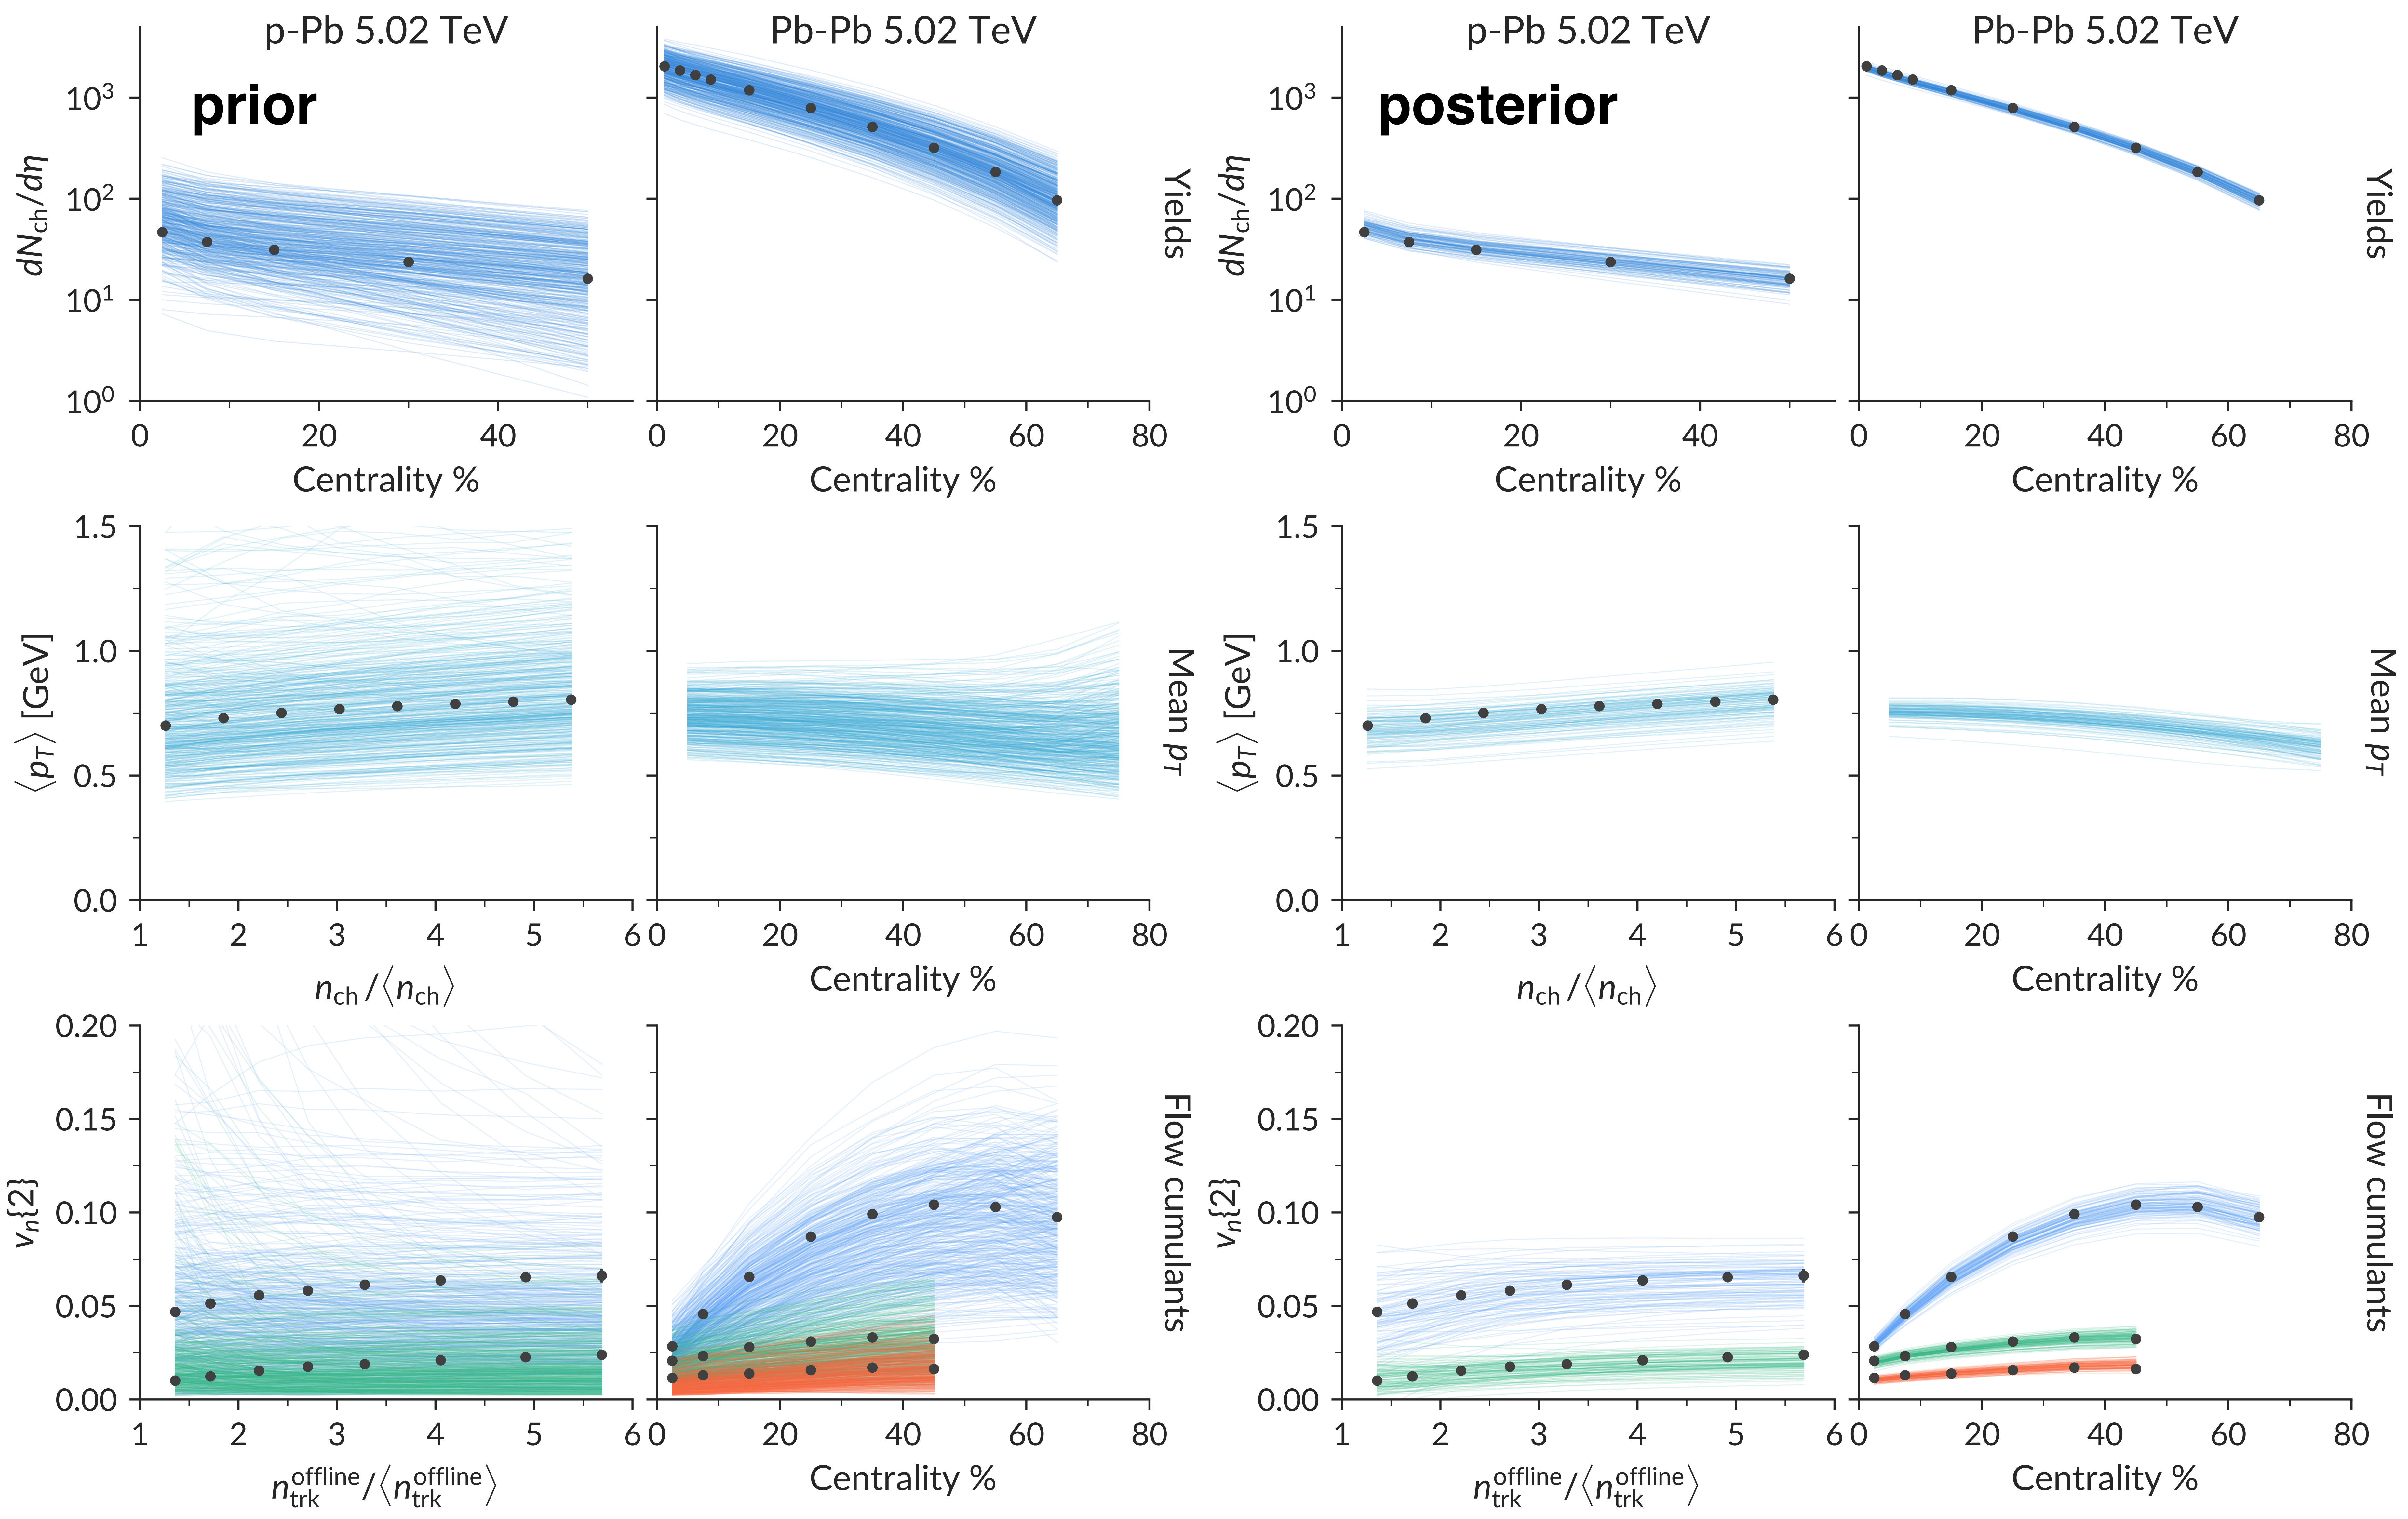
Trento with nucleon substructure:



- trade Gaussian nucleons for lumpy nucleons
- additional parameters:
  - sampling radius of constituent positions
  - constituent Gaussian width
  - number of constituents in each nucleon

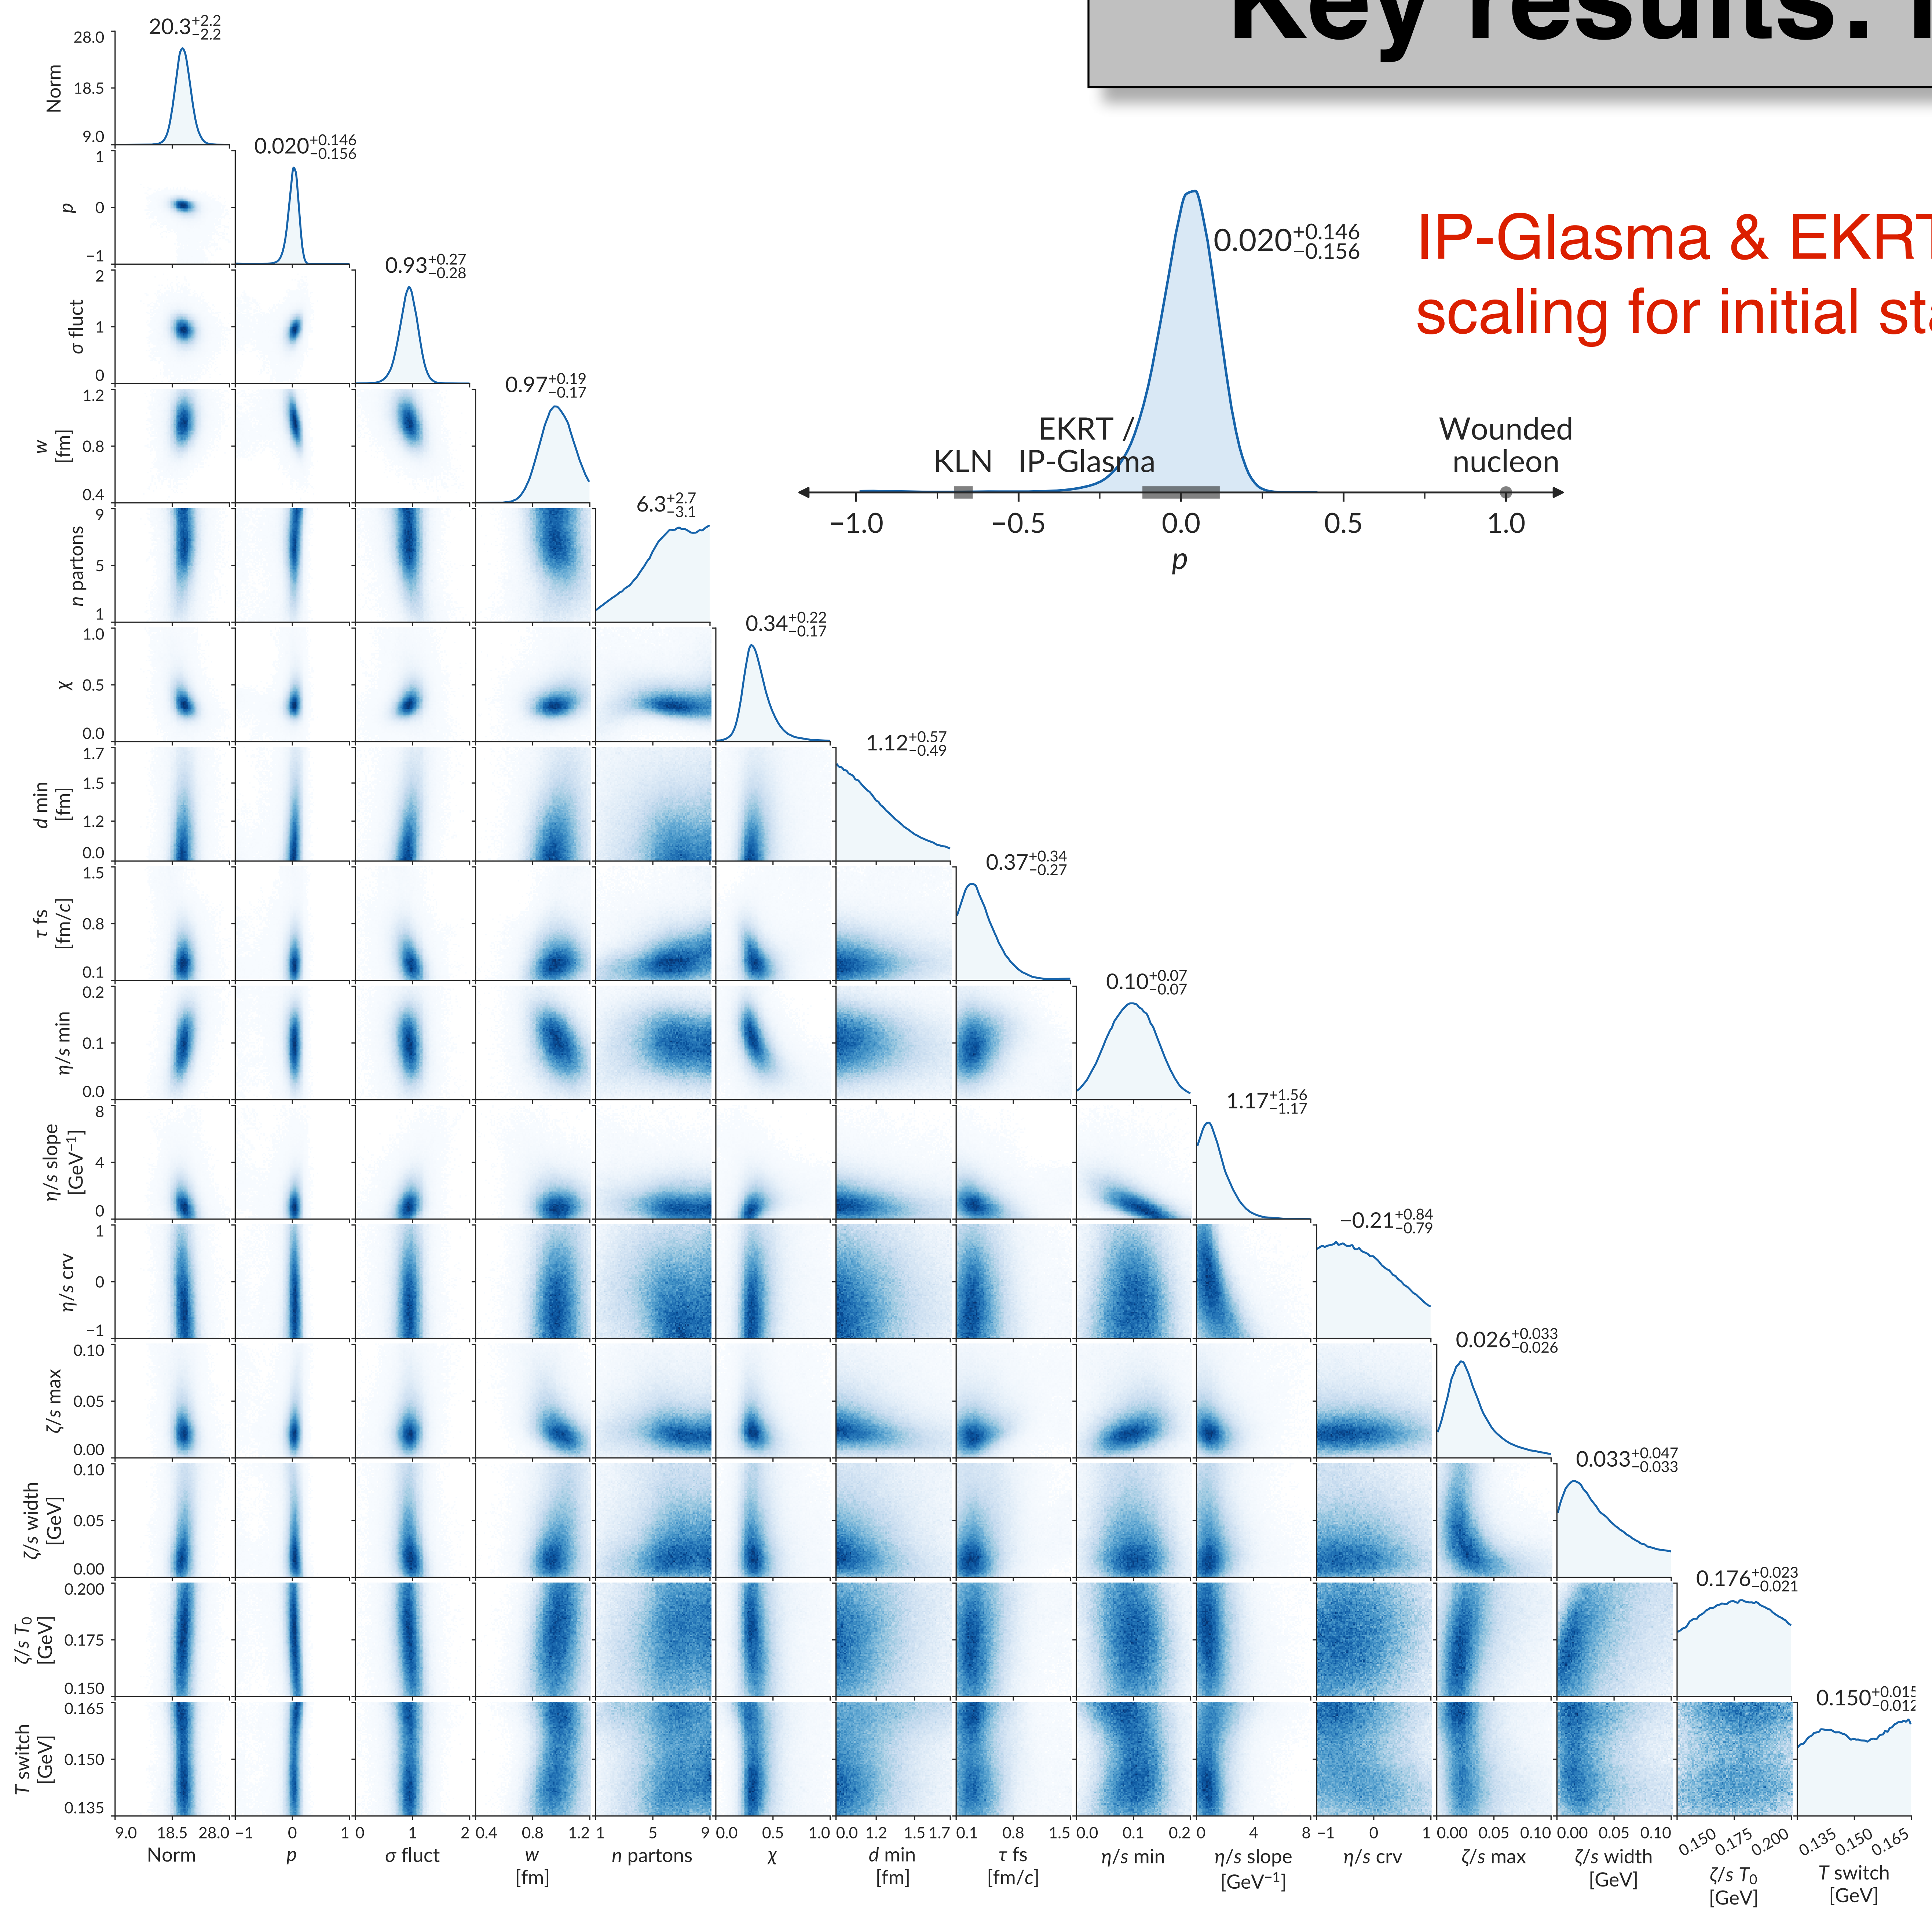


Simultaneous Calibration on AA and pA

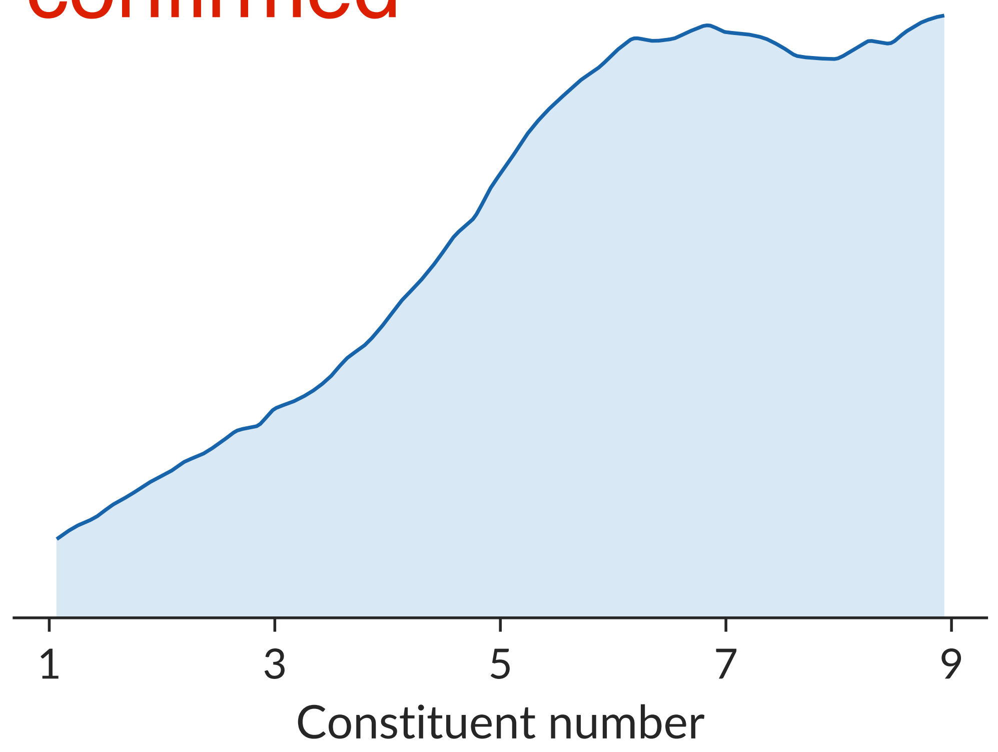


- ALICE & CMS data for AA & pA at 5.02 TeV
- calibration on 15 parameters, for initial state, shear and bulk viscosities
- restriction on 1 energy to keep computational effort reasonable
- generally larger uncertainties in posterior, due to less data than in the AA calibrations for 2 energies…

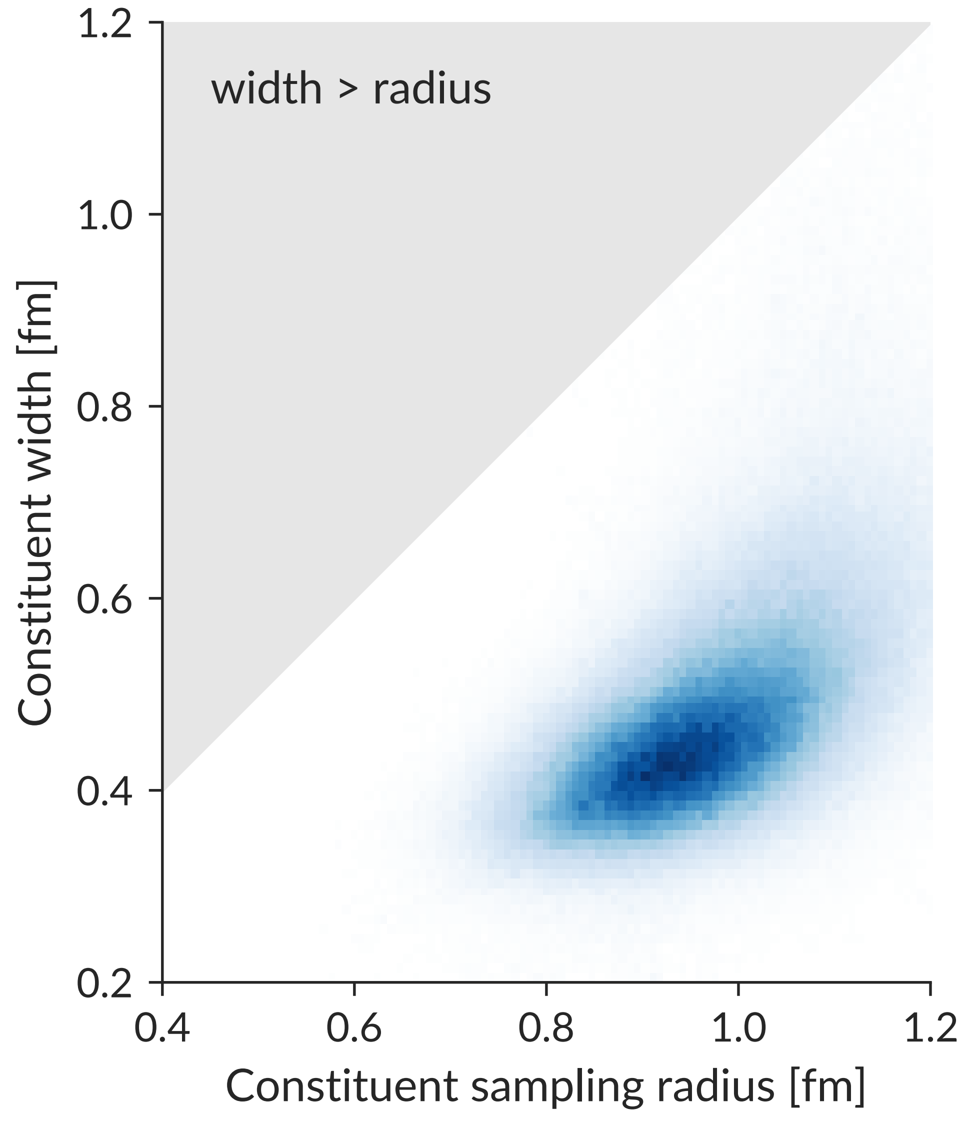
Key results: initial state



IP-Glasma & EKRT eccentricity scaling for initial state confirmed



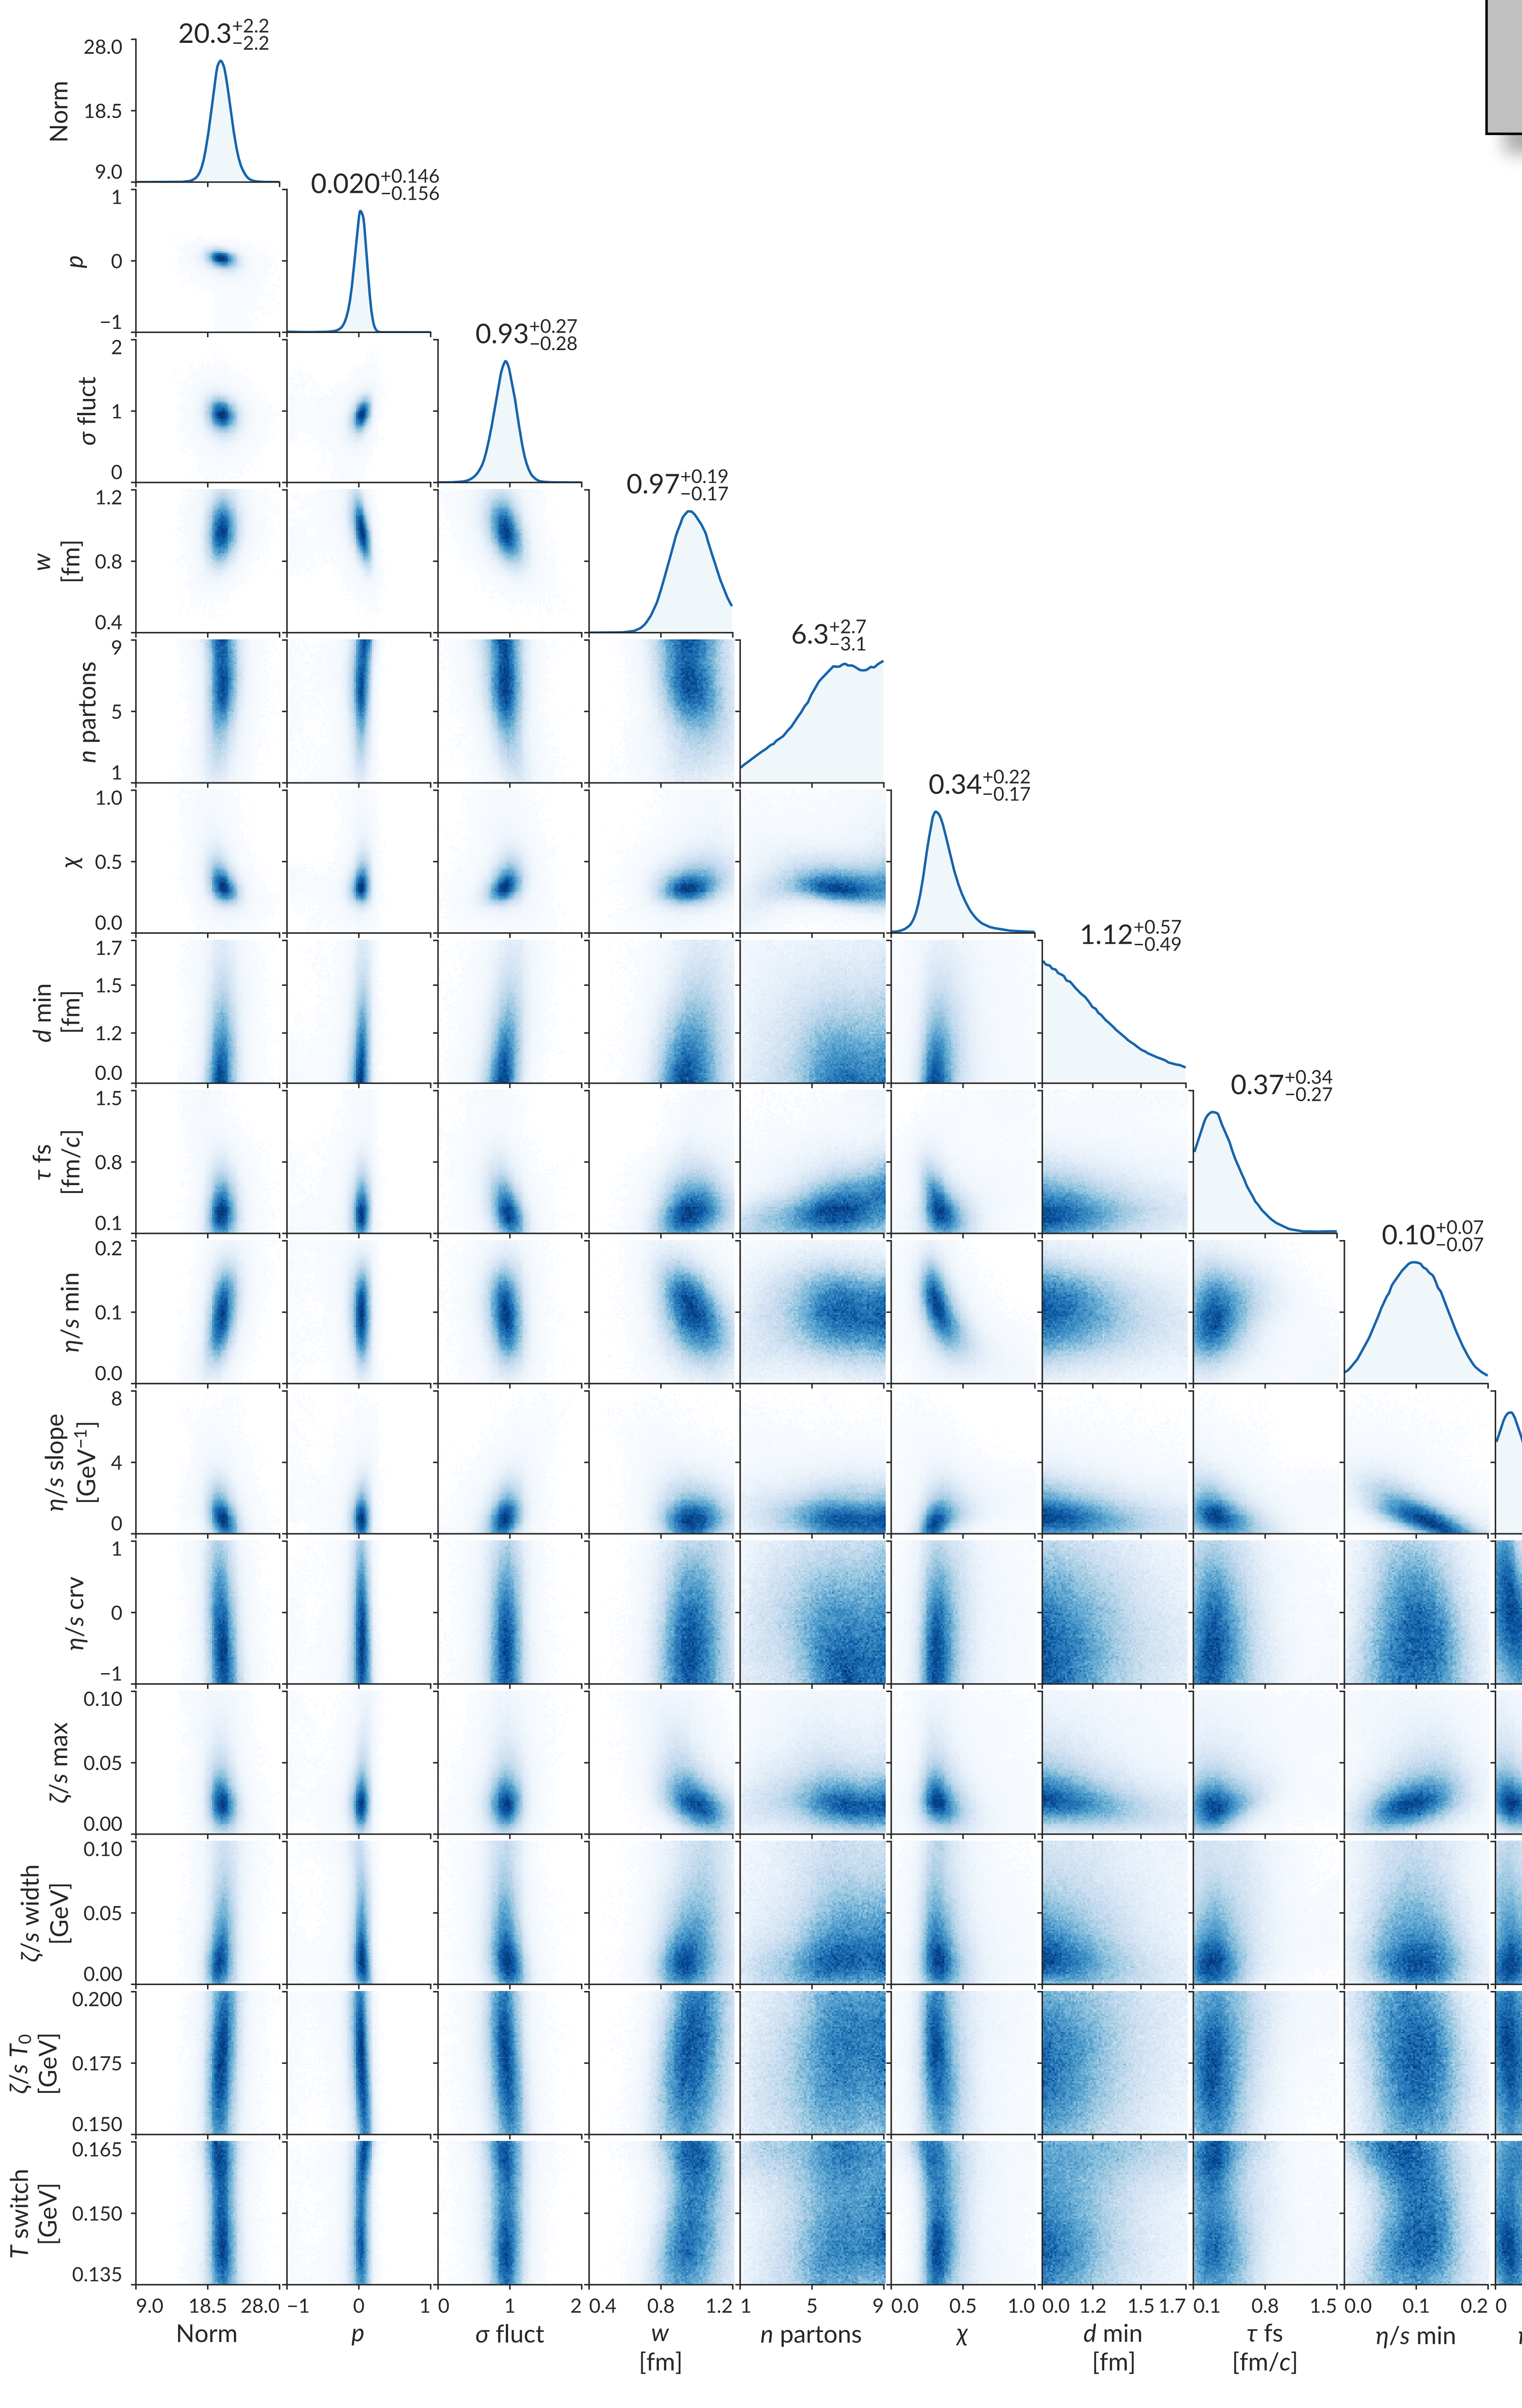
no strong preference for a particular constituent # as long as n>3

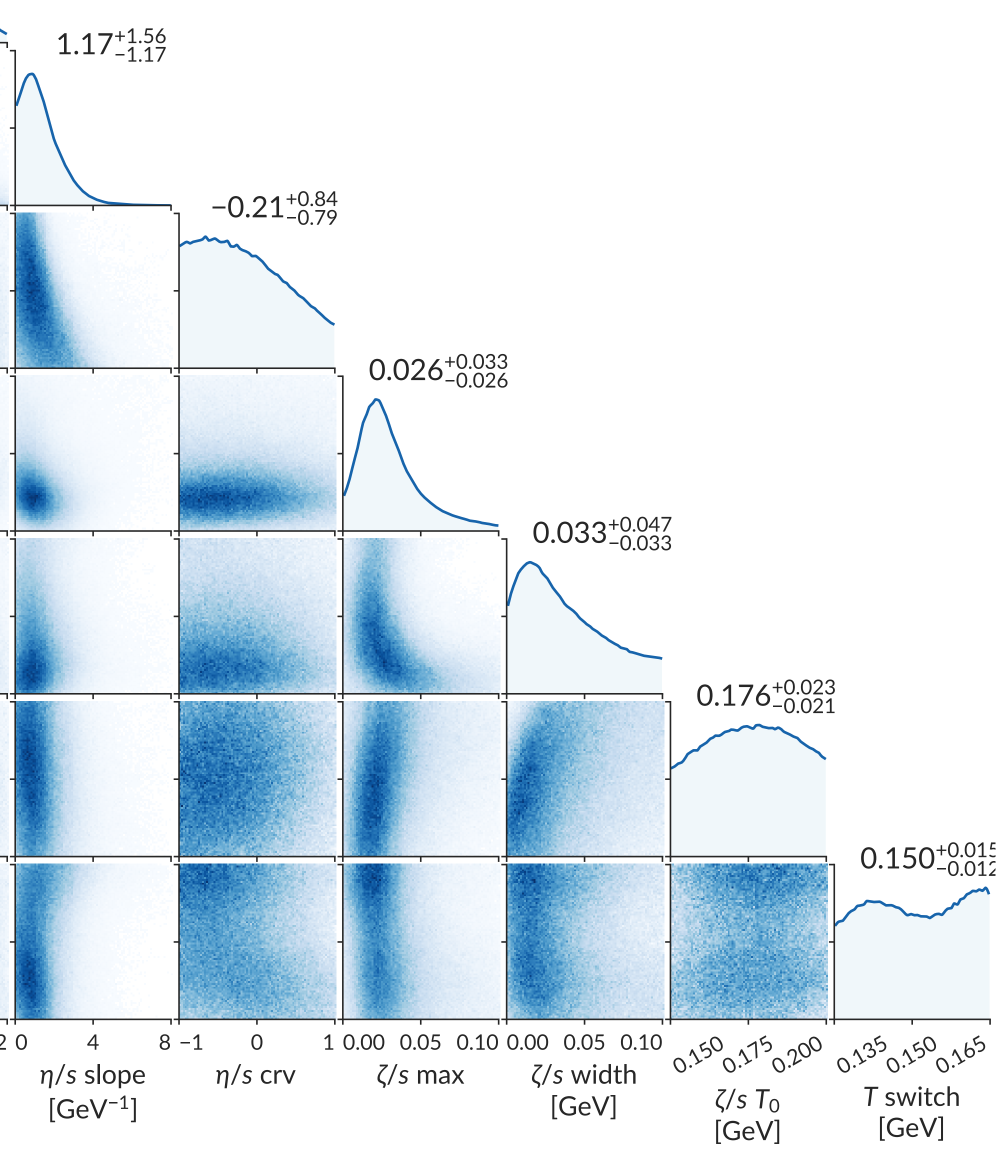


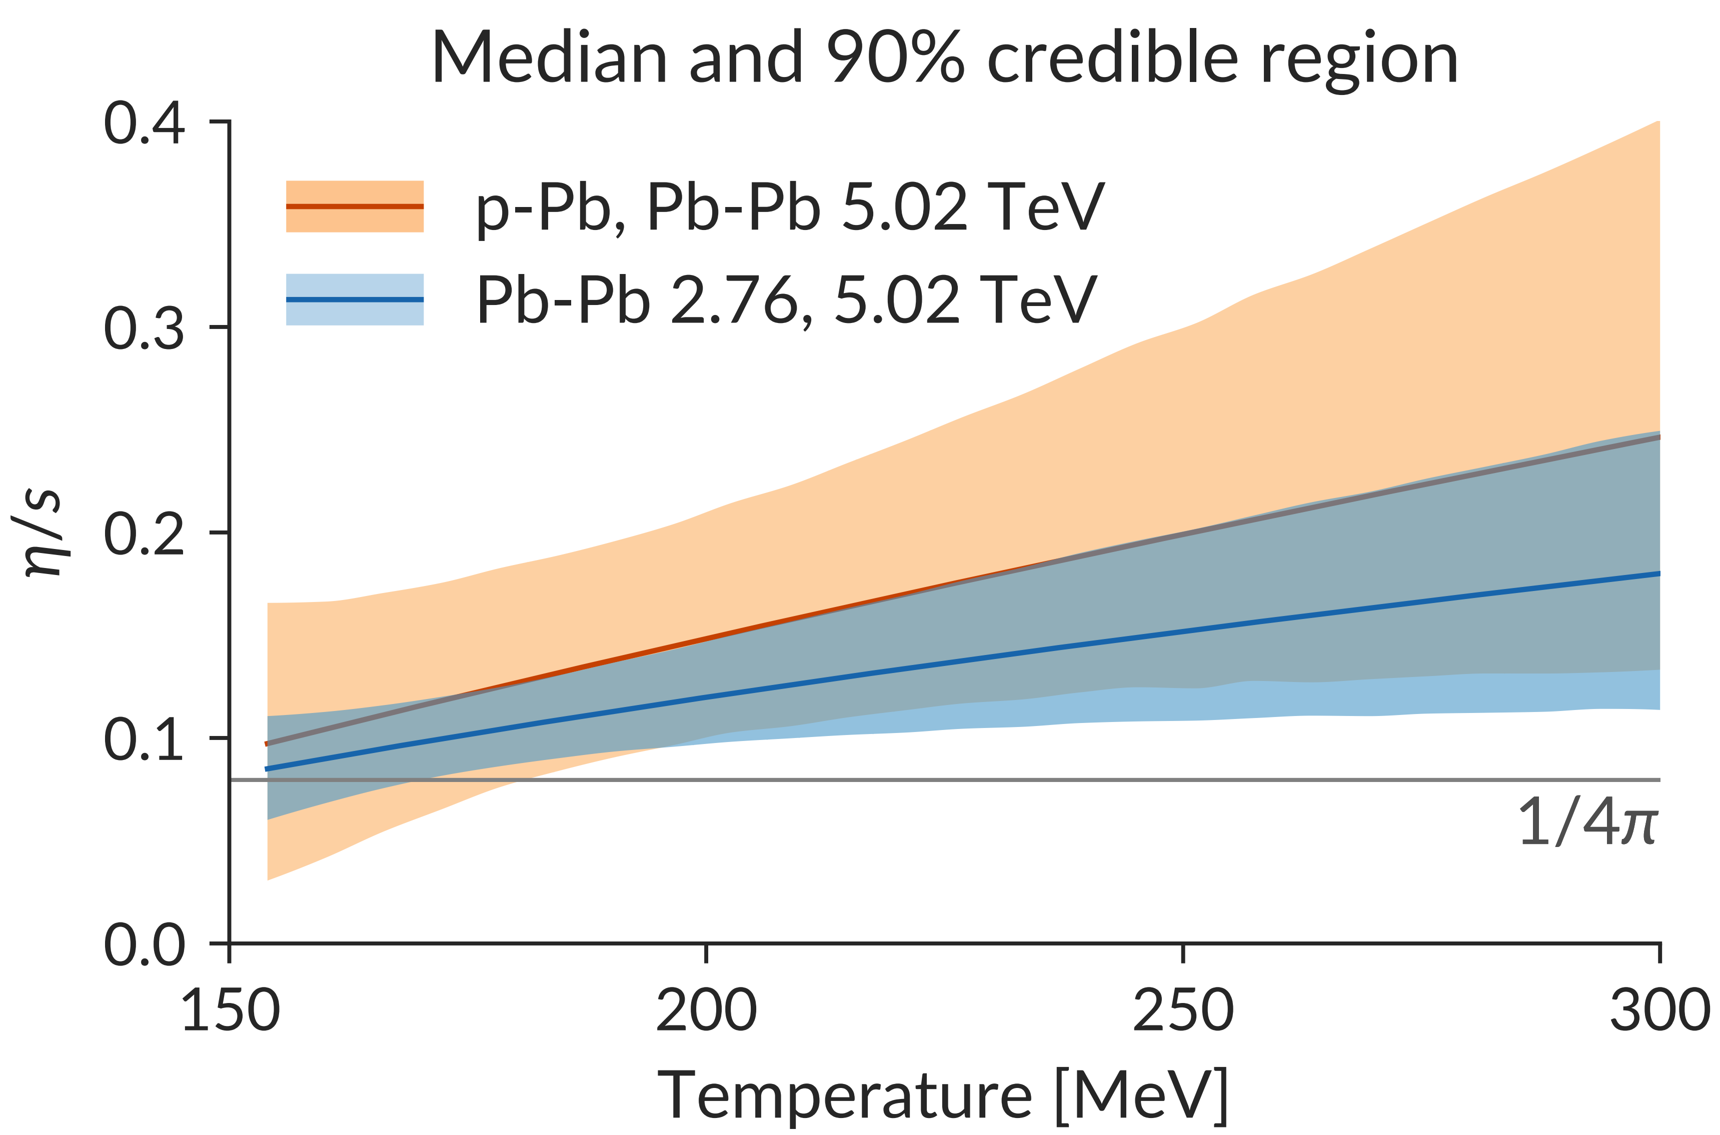
constituent width & sampling radius are well constrained to

- r = 0.99 ± 0.16
- w = 0.47 ± 0.18

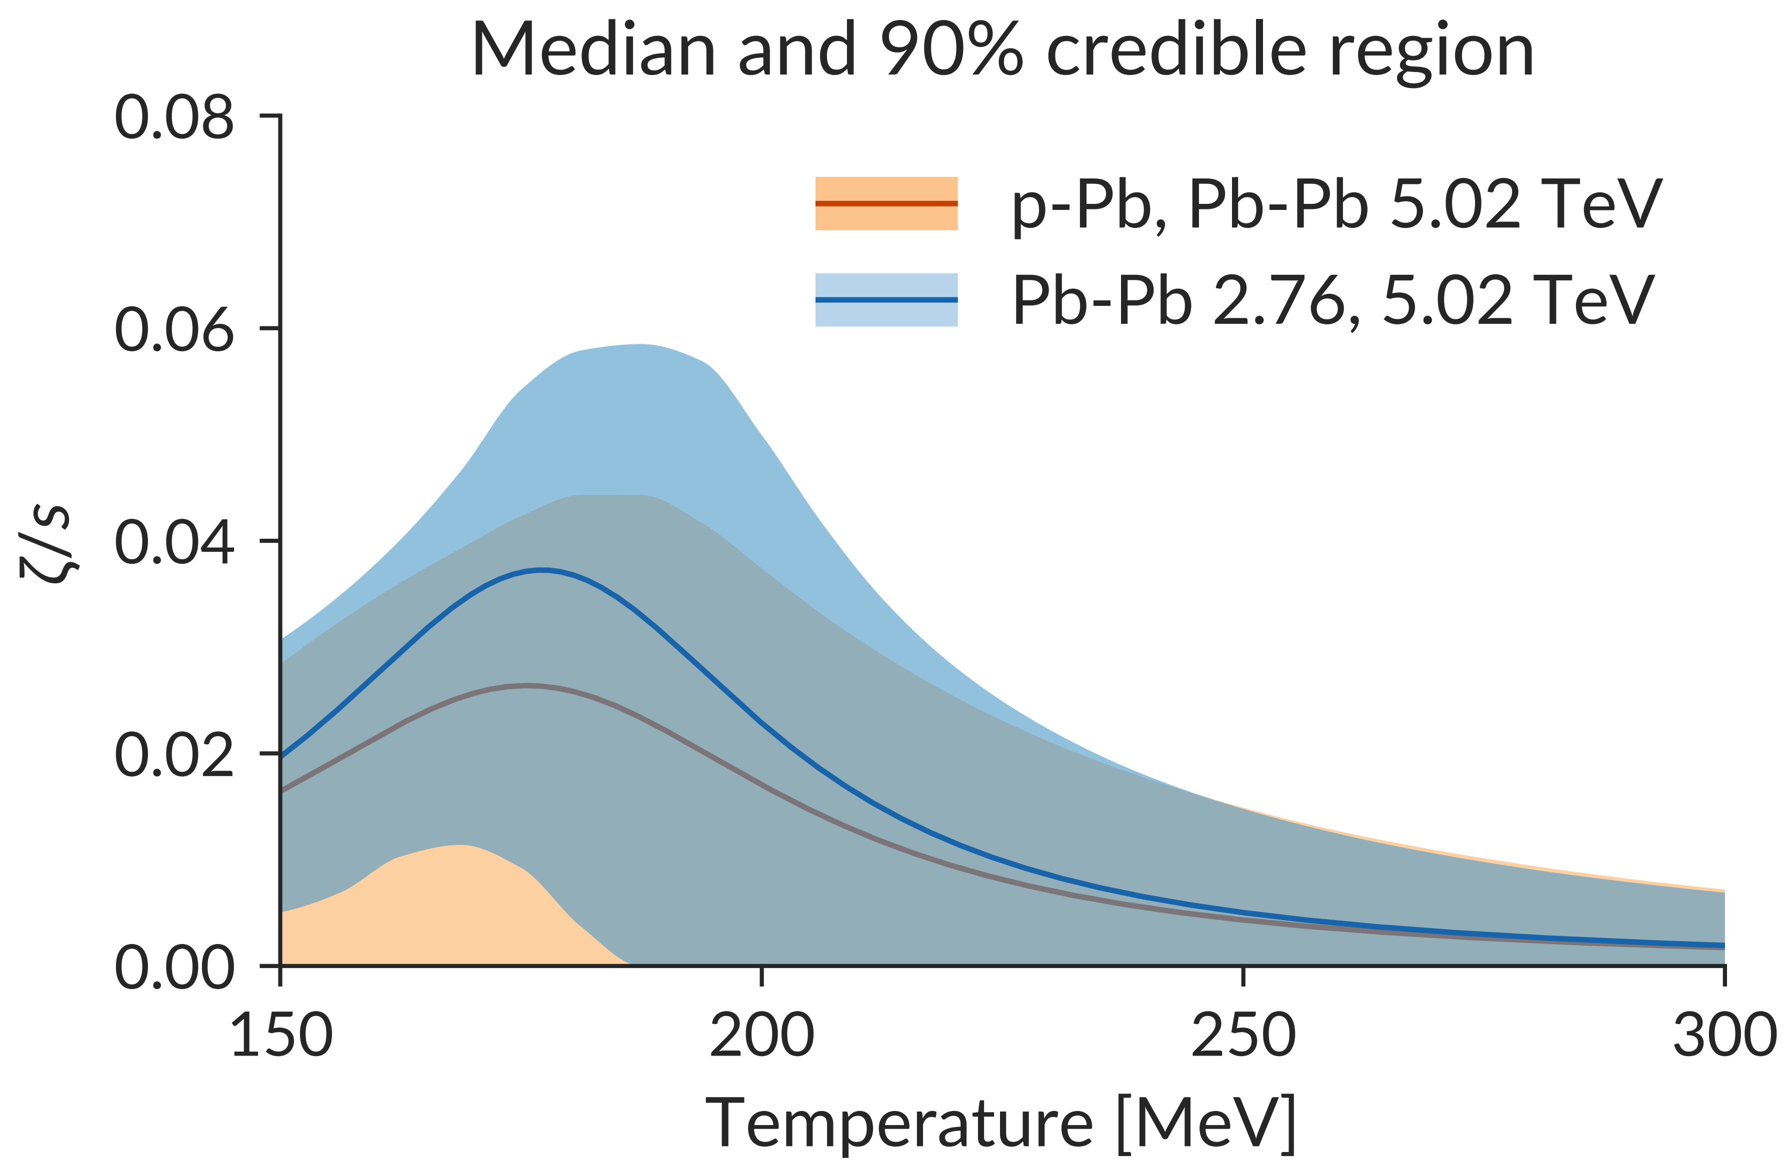
Key results: viscosities







- shear and bulk viscosities are fully compatible with previous calibration on Pb+Pb @ 2.76 TeV & 5.02 TeV
- uncertainty bands are larger in AA + pA analysis due to focus on single beam energy
- for bulk properties, multiple beam energies are more important than inclusion of small systems



Other Examples: Equation of State

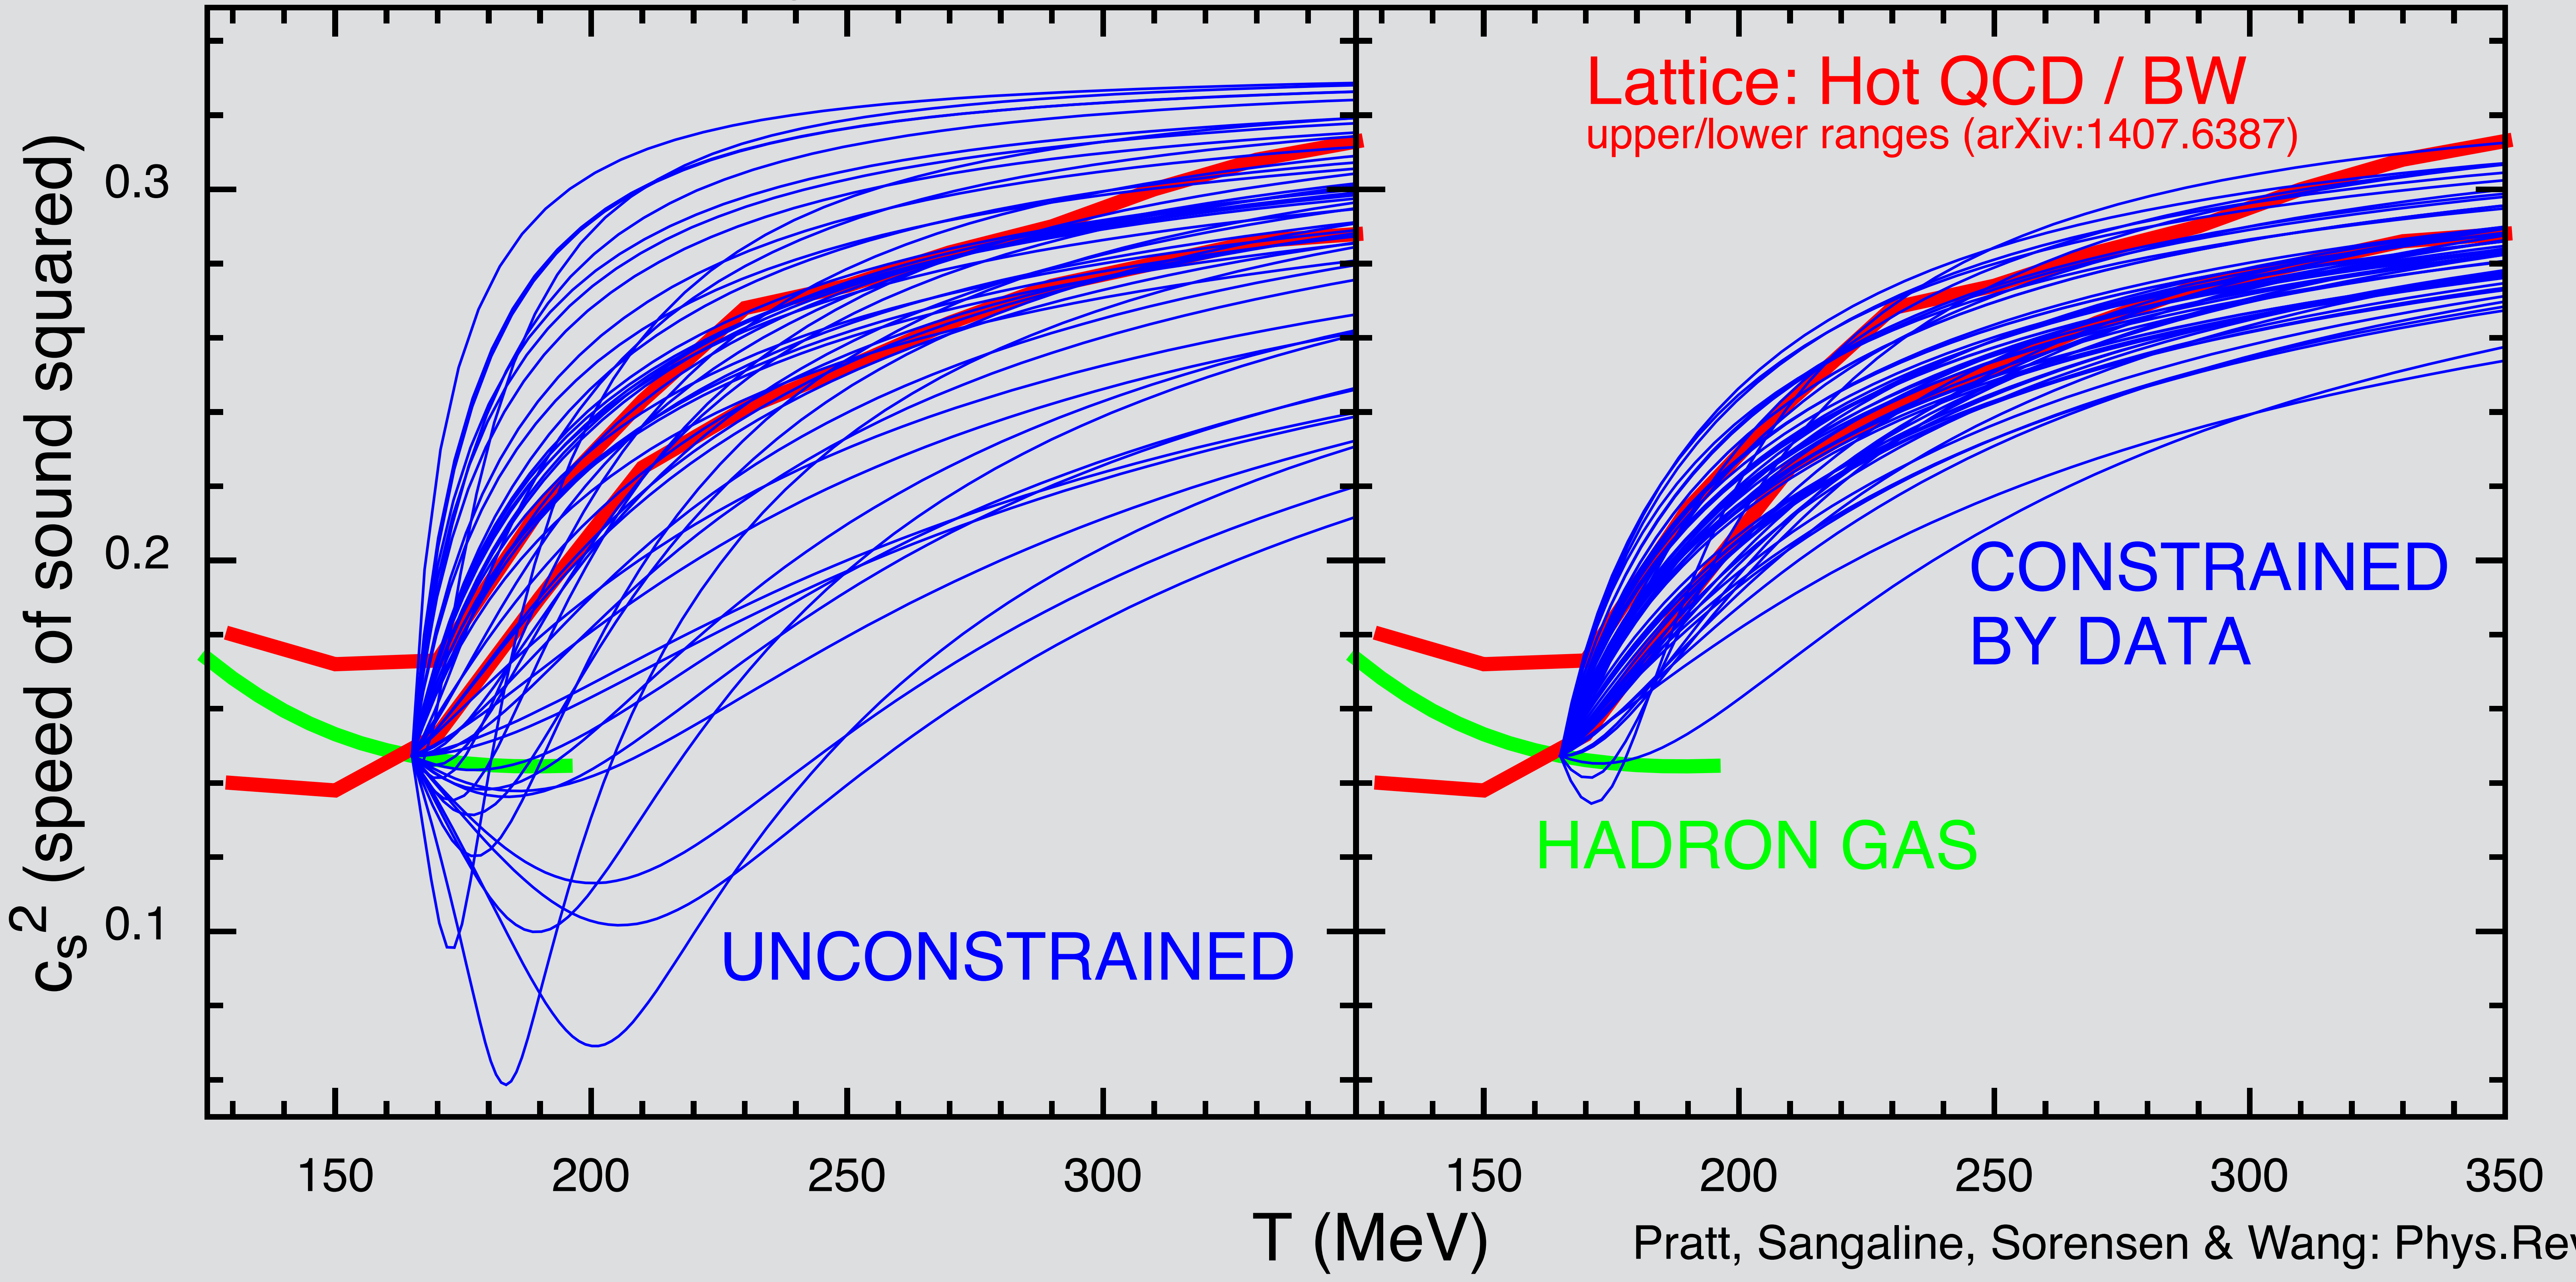
Example: determine the EoS of QGP matter from experimental measurements

what equation of state would the physics model choose to best describe the experimental data?

- create set of QCD Equations of State (aka the *prior*)
- run physics model with each EoS
- use comparison with RHIC/LHC data to determine which Equations of State are consistent with data (i.e. the *posterior*)

▸ **posterior is very similar to Lattice EoS!!**

Constraining Eq. of State with RHIC/LHC Data (MADAI Collab.)

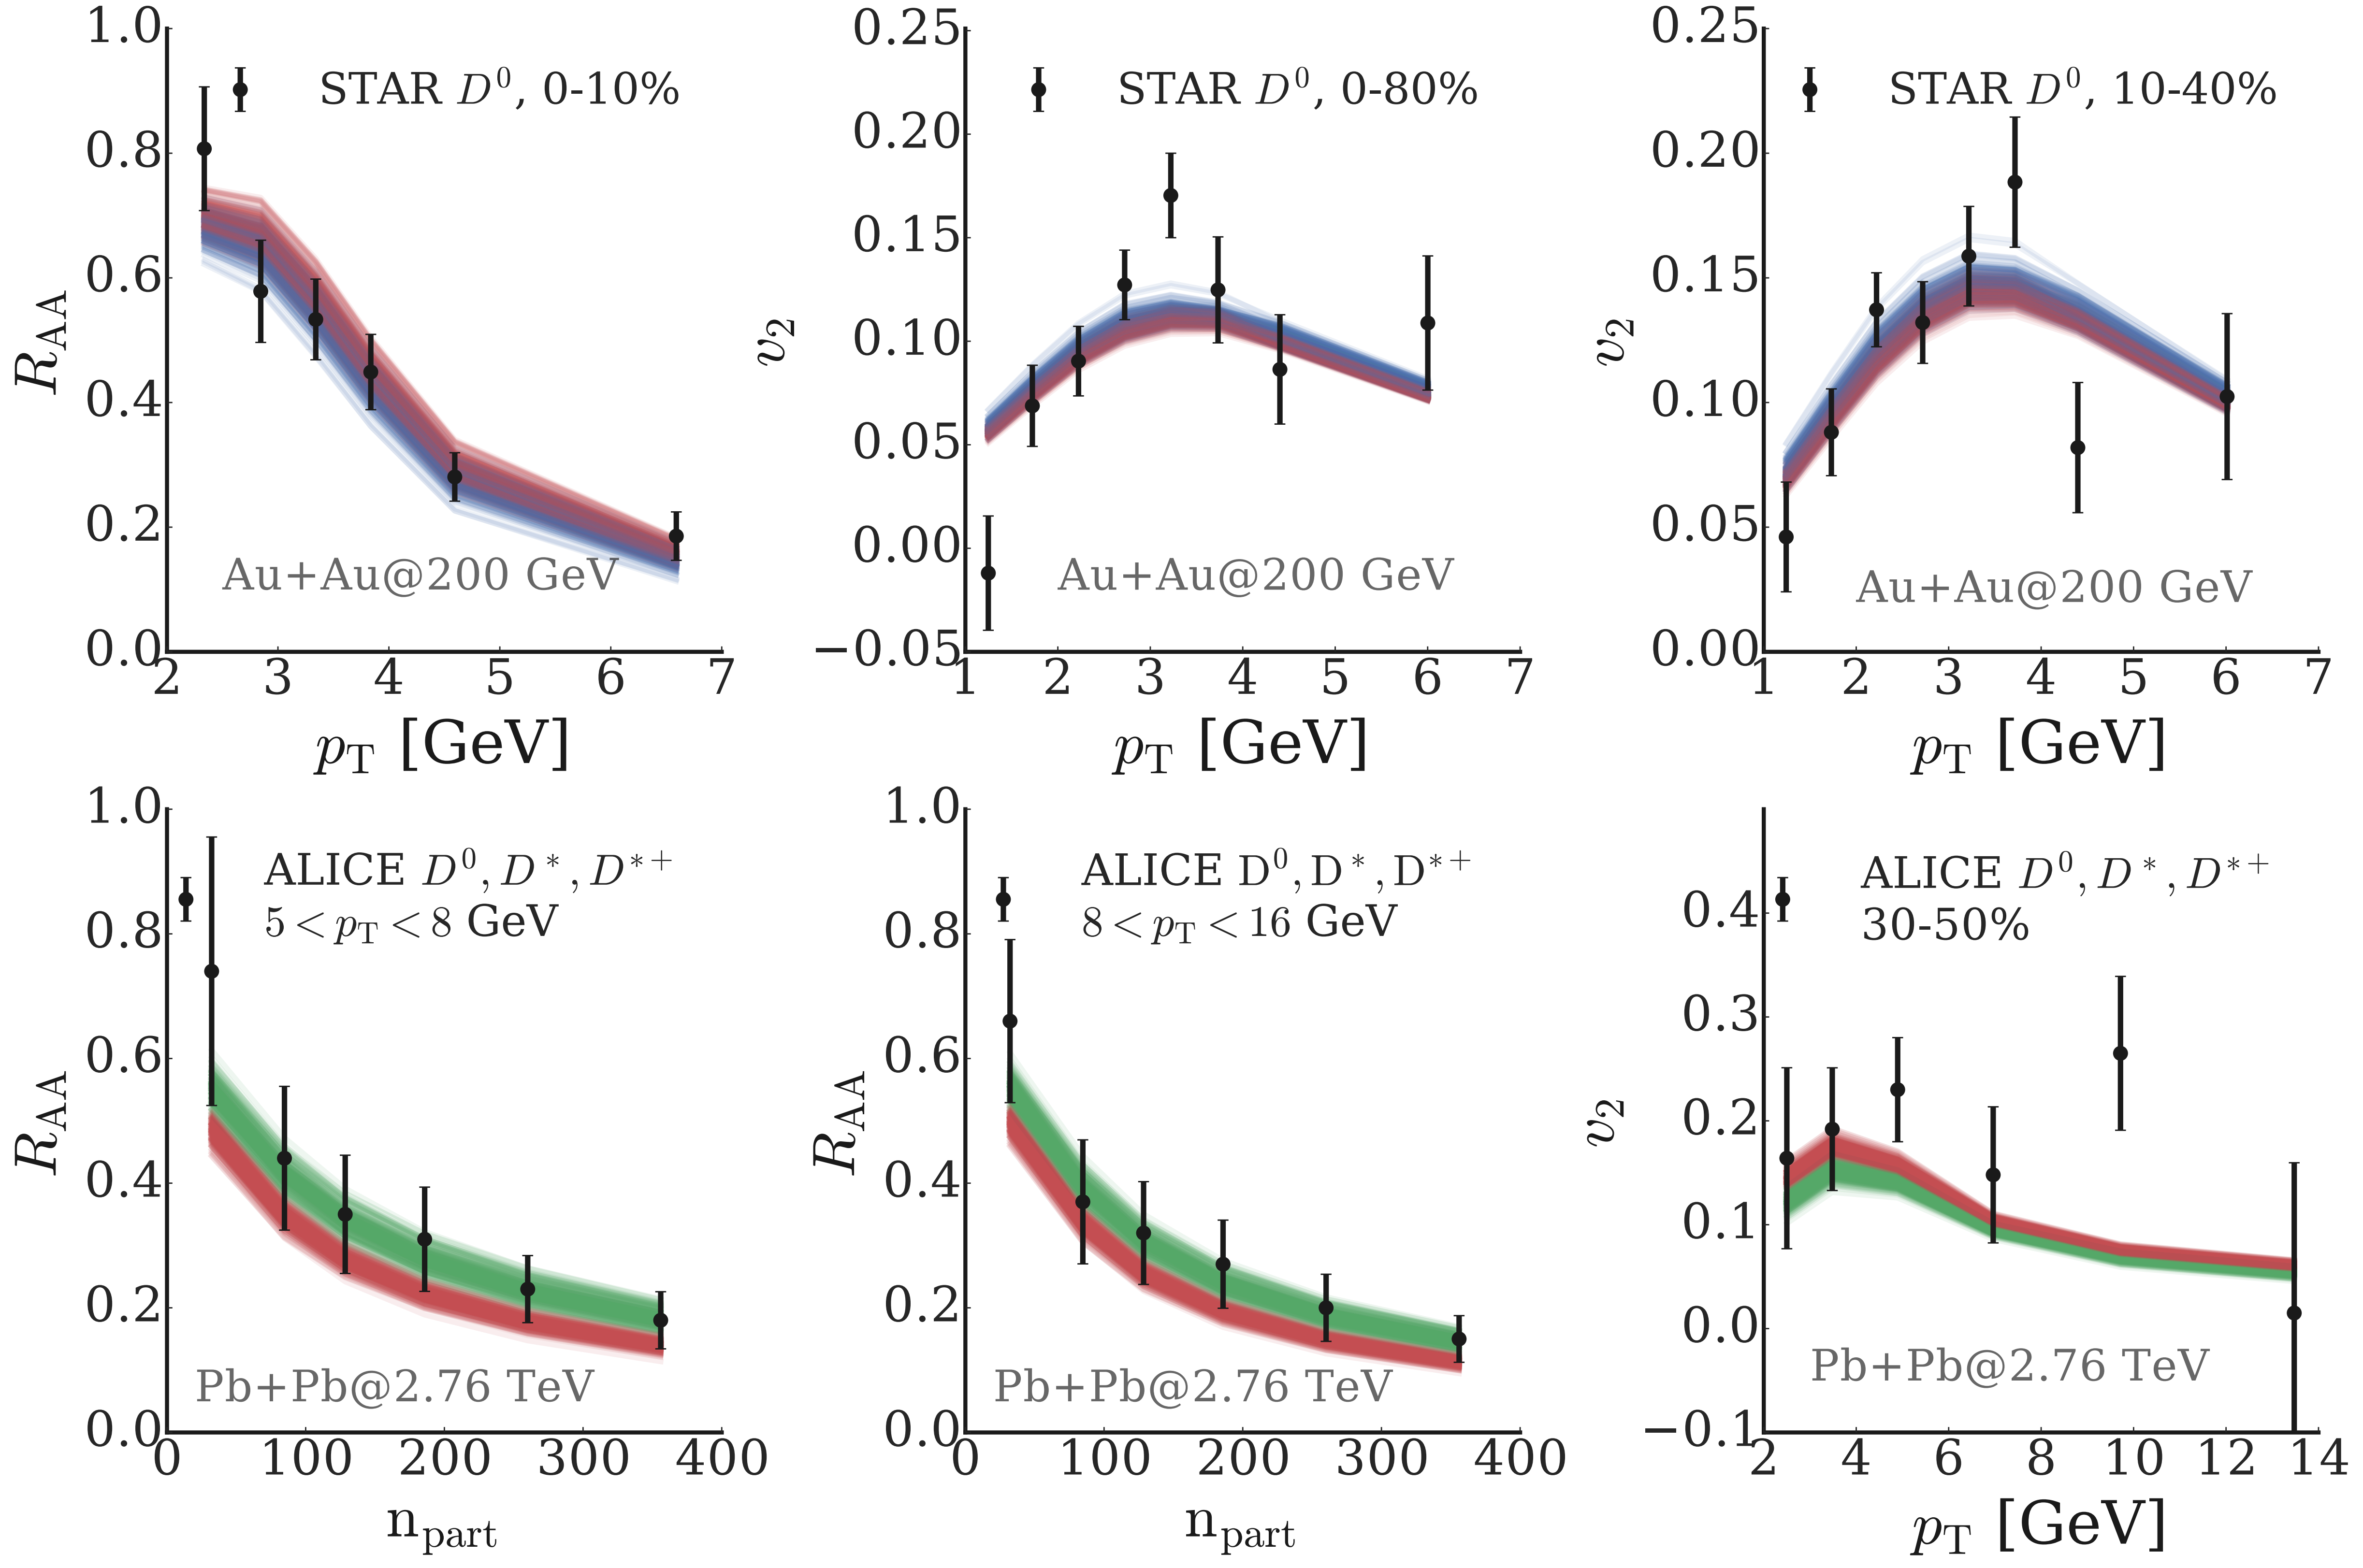


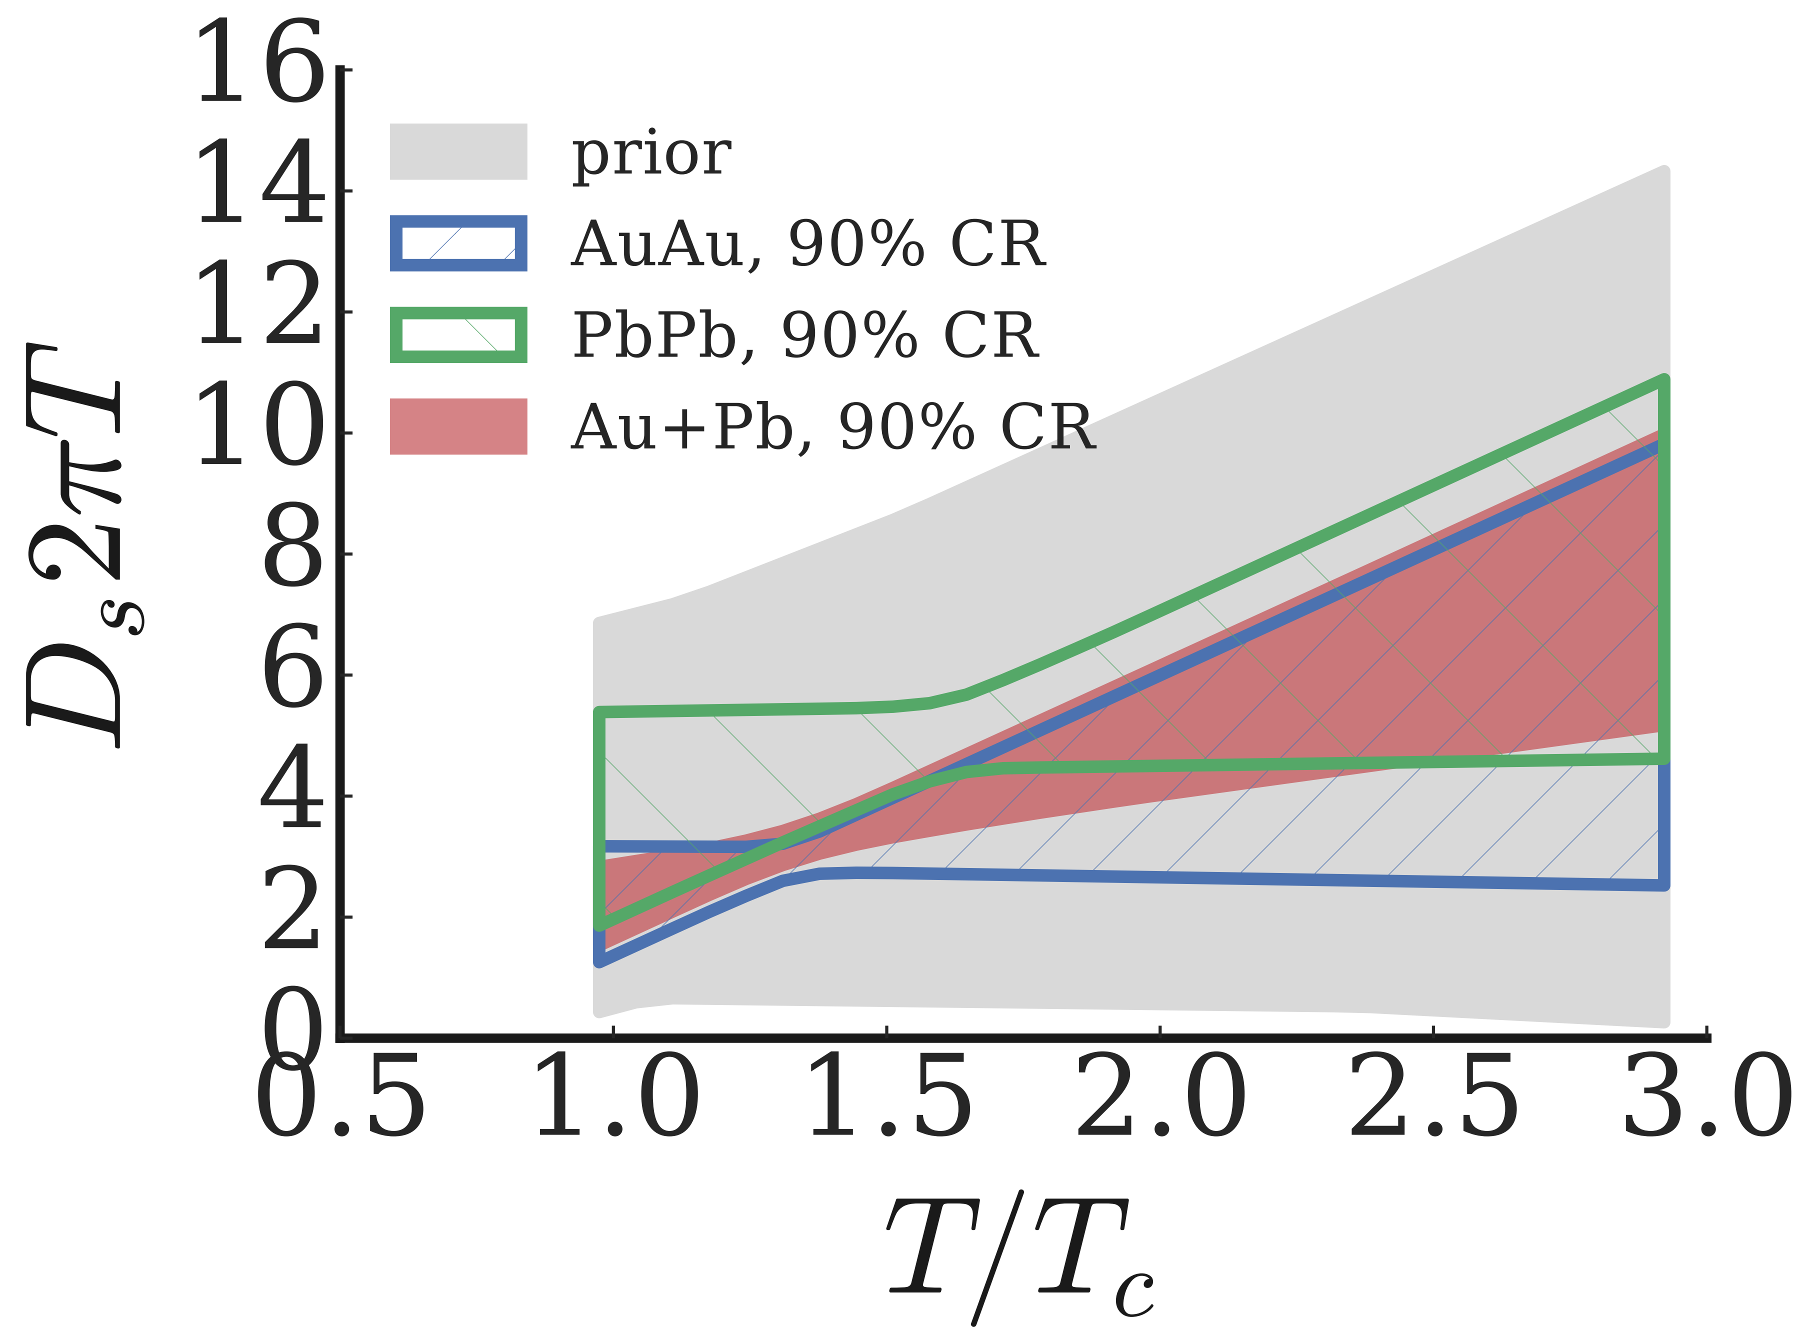
Pratt, Sangaline, Sorensen & Wang: Phys.Rev.Lett. **114** (2015) 202301

Other Examples: Heavy Quarks

Extraction of the Heavy Quark Diffusion Coefficient

- calibration on heavy quark v_2 and R_{AA}





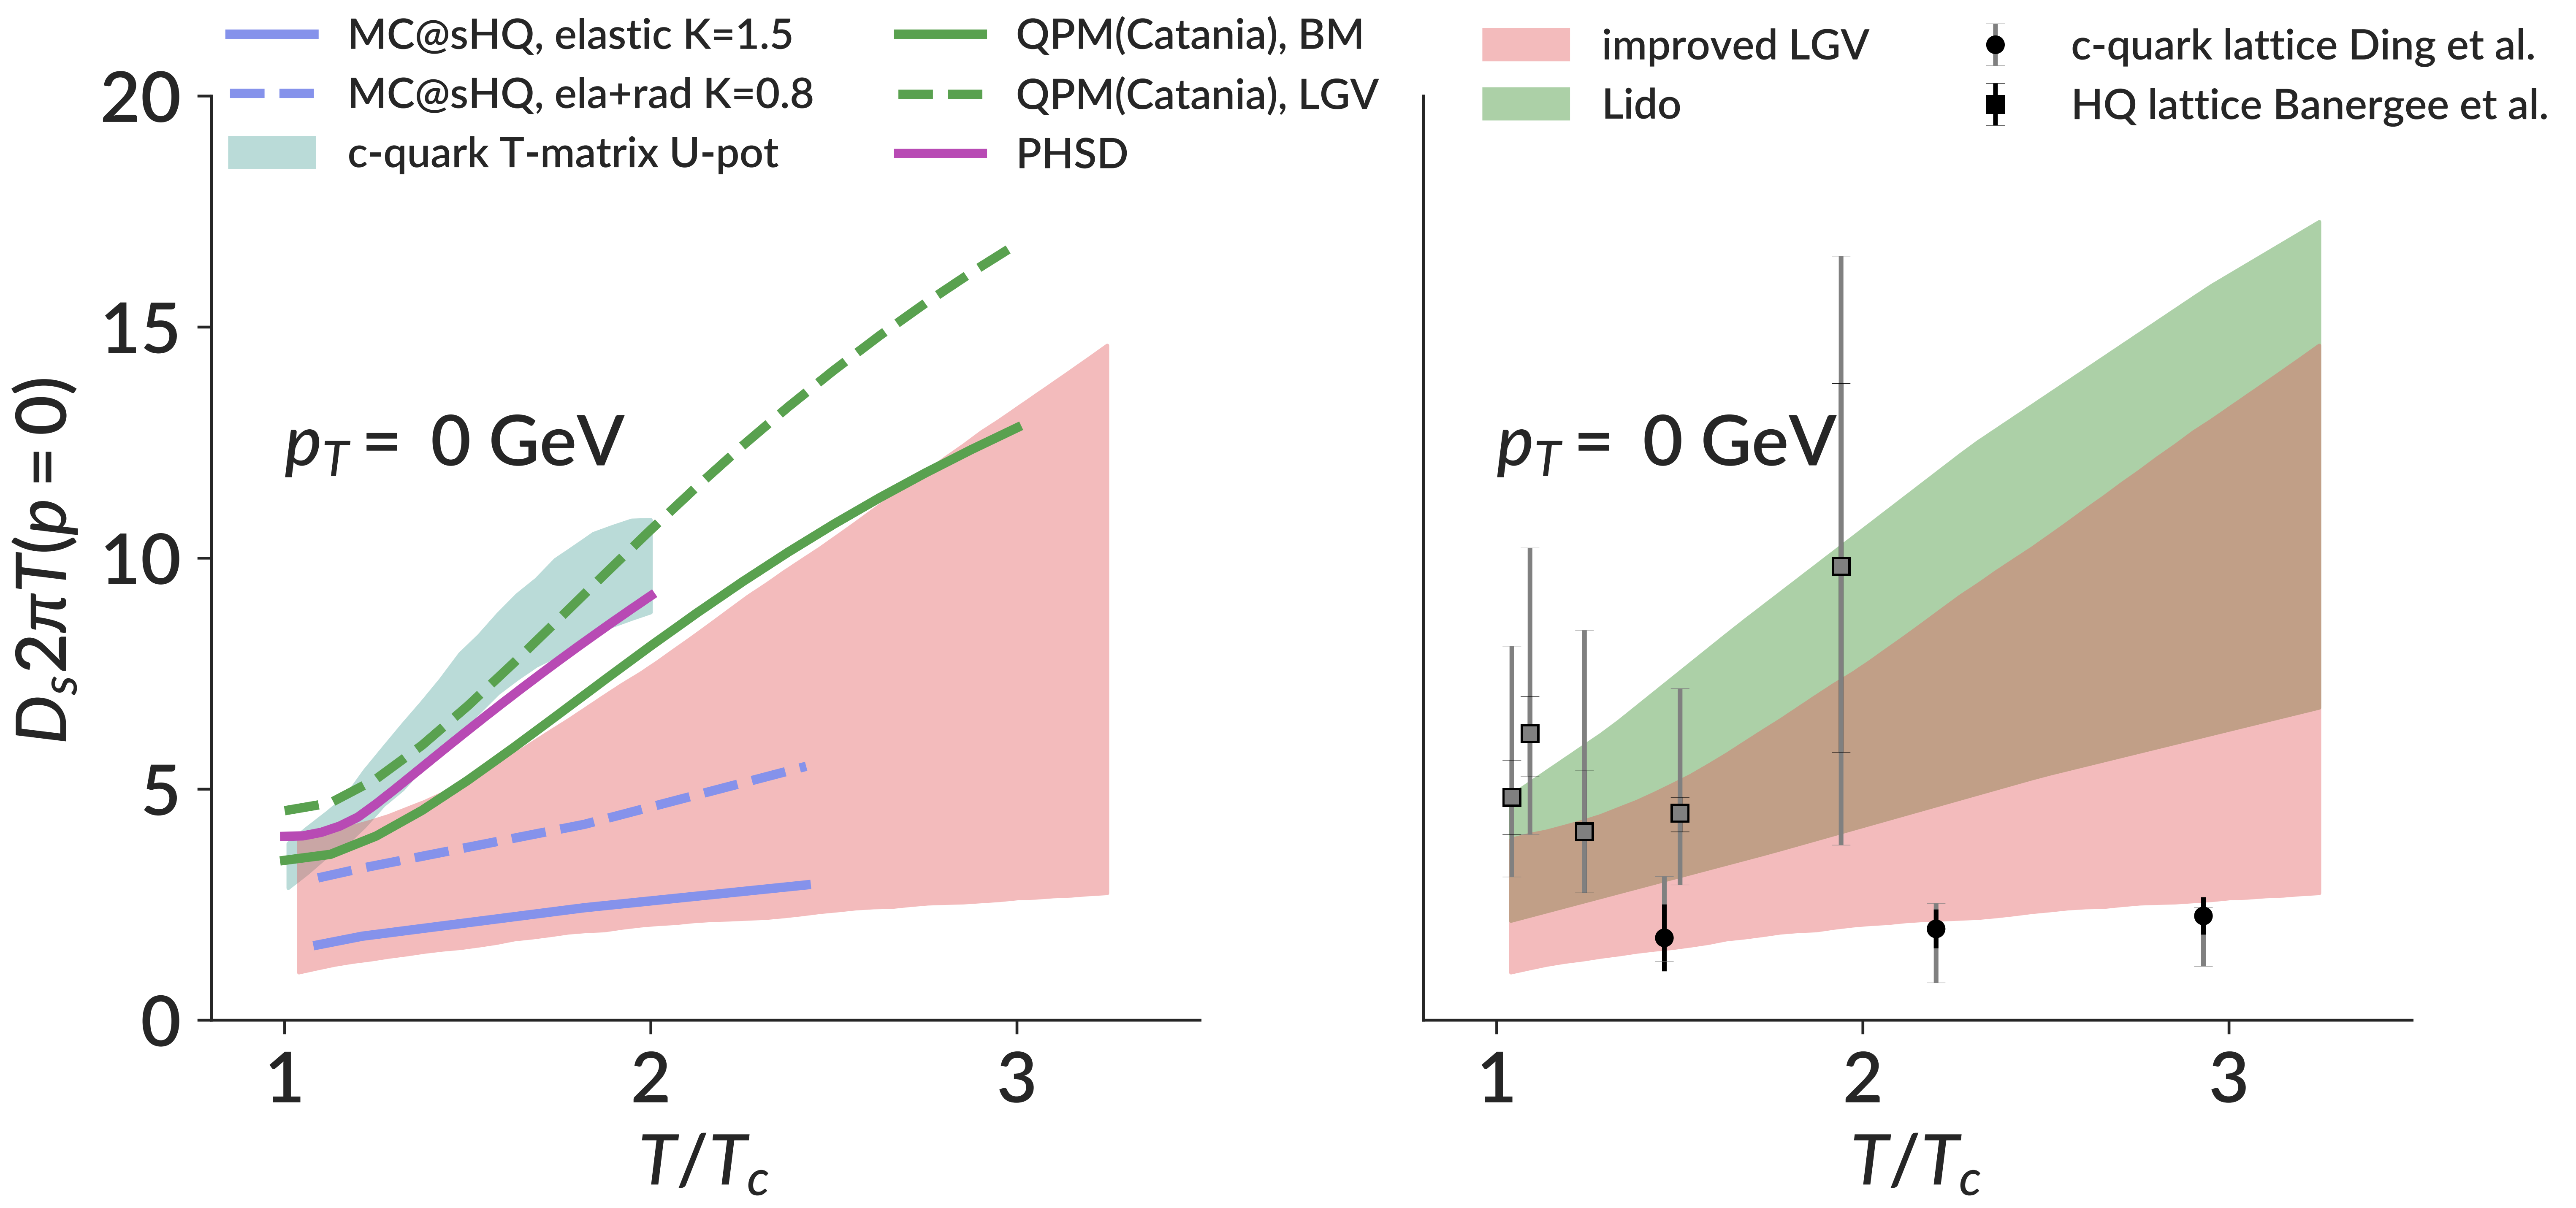
- combining RHIC and LHC data yields significant improvement for the extraction of $D_s(T)$

Y. Xu, J.E. Bernhard, S.A. Bass, M. Nahrgang & S. Cao: Phys. Rev C97 (2018) 014907

Other Applications: Heavy-Quark Transport Coefficient

first data-driven extraction of temperature & momentum dependence of D_s

- D_s significantly smaller than pQCD baseline at temperatures that can be probed at RHIC & LHC ($T<4T_C$)
- extracted D_s compatible with Lattice QCD within (large) uncertainties
- Lido prefers slightly larger D_s values than Langevin



caveats:
- need better data to reduce experimental uncertainties (& uncertainty-band)
- need additional observables to better constrain D_s

outlook:
- add more observables to analysis
- run analysis on different physics- and medium models to test robustness of D_s extraction
